

# Package ‘agtboost’

July 22, 2025

**Type** Package

**Title** Adaptive and Automatic Gradient Boosting Computations

**Version** 0.9.3

**Date** 2021-11-23

**Author** Berent Ånund Strømnes Lunde

**Maintainer** Berent Ånund Strømnes Lunde <lundeberent@gmail.com>

**Description** Fast and automatic gradient tree boosting designed to avoid manual tuning and cross-validation by utilizing an information theoretic approach. This makes the algorithm adaptive to the dataset at hand; it is completely automatic, and with minimal worries of overfitting. Consequently, the speed-ups relative to state-of-the-art implementations can be in the thousands while mathematical and technical knowledge required on the user are minimized.

**License** GPL-3

**Encoding** UTF-8

**LazyData** true

**Depends** R (>= 3.6.0)

**Imports** methods, Rcpp (>= 1.0.1)

**LinkingTo** Rcpp, RcppEigen

**RcppModules** aGTBModule

**RoxygenNote** 7.1.2

**Suggests** testthat

**NeedsCompilation** yes

**Repository** CRAN

## Description

Adaptive and Automatic Gradient Boosting Computations

## Details

**agtboost** is a lightning fast gradient boosting library designed to avoid manual tuning and cross-validation by utilizing an information theoretic approach. This makes the algorithm adaptive to the dataset at hand; it is completely automatic, and with minimal worries of overfitting. Consequently, the speed-ups relative to state-of-the-art implementations are in the thousands while mathematical and technical knowledge required on the user are minimized.

Important functions:

- `gbt.train`: function for training an **agtboost** ensemble
- `predict.Rcpp_ENSEMBLE`: function for predicting from an **agtboost** ensemble

See individual function documentation for usage.

---

`caravan.train`*The Insurance Company (TIC) Benchmark*

---

## Description

`caravan.train` and `caravan.test` both contain a design matrix with 85 columns and a response vector. The train set consists of 70% of the data, with 4075 rows. The test set consists of the remaining 30% with 1747 rows. The following references the documentation within the **ISLR** package: The original data contains 5822 real customer records. Each record consists of 86 variables, containing sociodemographic data (variables 1-43) and product ownership (variables 44-86). The sociodemographic data is derived from zip codes. All customers living in areas with the same zip code have the same sociodemographic attributes. Variable 86 (Purchase) indicates whether the customer purchased a caravan insurance policy. Further information on the individual variables can be obtained at <http://www.liacs.nl/~putten/library/cc2000/data.html>

## Usage

```
caravan.train; caravan.test
```

## Format

Lists with a design matrix  $x$  and response  $y$

## Source

The data was originally supplied by Sentient Machine Research and was used in the CoIL Challenge 2000.

## Examples

```
summary(caravan.train)  
summary(caravan.test)
```

---

gbt.complexity	<i>Return complexity of model in terms of hyperparameters.</i>
----------------	--

---

### Description

gbt.complexity creates a list of hyperparameters from a model

### Usage

```
gbt.complexity(model, type)
```

### Arguments

model	object or pointer to object of class ENSEMBLE
type	currently supports "xgboost" or "lightgbm"

### Details

Returns the complexity of model in terms of hyperparameters associated to model type.

### Value

list with type hyperparameters.

### Examples

```
set.seed(123)
library(agtboost)
n <- 10000
xtr <- as.matrix(runif(n, 0, 4))
ytr <- rnorm(n, xtr, 1)
xte <- as.matrix(runif(n, 0, 4))
yte <- rnorm(n, xte, 1)
model <- gbt.train(ytr, xtr, learning_rate = 0.1)
gbt.complexity(model, type="xgboost")
gbt.complexity(model, type="lightgbm")
## See demo(topic="gbt-complexity", package="agtboost")
```

---

gbt.convergence	<i>Convergence of agtboost model.</i>
-----------------	---------------------------------------

---

## Description

gbt.convergence calculates loss of data over iterations in the model

## Usage

```
gbt.convergence(object, y, x)
```

## Arguments

object	Object or pointer to object of class ENSEMBLE
y	response vector
x	design matrix for training. Must be of type matrix.

## Details

Computes the loss on supplied data at each boosting iterations of the model passed as object. This may be used to visually test for overfitting on test data, or the converge, to check for underfitting or non-convergence.

## Value

vector with  $K+1$  elements with loss at each boosting iteration and at the first constant prediction

## Examples

```
## Gaussian regression:
x_tr <- as.matrix(runif(500, 0, 4))
y_tr <- rnorm(500, x_tr, 1)
x_te <- as.matrix(runif(500, 0, 4))
y_te <- rnorm(500, x_te, 1)
mod <- gbt.train(y_tr, x_tr)
convergence <- gbt.convergence(mod, y_te, x_te)
which.min(convergence) # Should be fairly similar to boosting iterations + 1
mod$get_num_trees() + 1 # num_trees does not include initial prediction
```

---

gbt.importance	<i>Importance of features in a model.</i>
----------------	---

---

## Description

gbt.importance creates a data.frame of feature importance in a model

## Usage

```
gbt.importance(feature_names, object)
```

## Arguments

feature\_names character vector of feature names  
object object or pointer to object of class ENSEMBLE

## Details

Sums up "expected reduction" in generalization loss (scaled using learning\_rate) at each node for each tree in the model, and attributes it to the feature the node is split on. Returns result in terms of percents.

## Value

data.frame with percentwise reduction in loss of total attributed to each feature.

## Examples

```
## Load data
data(caravan.train, package = "agtboost")
train <- caravan.train
mod <- gbt.train(train$y, train$x, loss_function = "logloss", verbose=10)
feature_names <- colnames(train$x)
imp <- gbt.importance(feature_names, mod)
imp
```

gbt.ksval

*Kolmogorov-Smirnov validation of model***Description**

gbt.ksval transforms observations to  $U(0,1)$  if the model is correct and performs a Kolmogorov-Smirnov test for uniformity.

**Usage**

```
gbt.ksval(object, y, x)
```

**Arguments**

object	Object or pointer to object of class ENSEMBLE
y	Observations to be tested
x	design matrix for training. Must be of type matrix.

**Details**

Model validation of model passed as object using observations  $y$ . Assuming the loss is a negative log-likelihood and thus a probabilistic model, the transformation

$$u = F_Y(y; x, \theta) \sim U(0, 1),$$

is usually valid. One parameter,  $\mu = g^{-1}(f(x))$ , is given by the model. Remaining parameters are estimated globally over feature space, assuming they are constant. This then allow the above transformation to be exploited, so that the Kolmogorov-Smirnov test for uniformity can be performed.

If the response is a count model (poisson or negbinom), the transformation

$$u_i = F_Y(y_i - 1; x, \theta) + U f_Y(y_i, x, \theta), \quad U \sim U(0, 1)$$

is used to obtain a continuous transformation to the unit interval, which, if the model is correct, will give standard uniform random variables.

**Value**

Kolmogorov-Smirnov test of model

**Examples**

```
## Gaussian regression:
x_tr <- as.matrix(runif(500, 0, 4))
y_tr <- rnorm(500, x_tr, 1)
x_te <- as.matrix(runif(500, 0, 4))
y_te <- rnorm(500, x_te, 1)
mod <- gbt.train(y_tr, x_tr)
gbt.ksval(mod, y_te, x_te)
```

`gbt.load` *Load an aGTBoost Model*

---

### Description

`gbt.load` is an interface for loading a **agtboost** model.

### Usage

```
gbt.load(file)
```

### Arguments

`file` Valid file-path to a stored aGTBoost model

### Details

The load function for **agtboost**. Loads a GTB model from a txt file.

### Value

Trained aGTBoost model.

### See Also

[gbt.save](#)

---

`gbt.save` *Save an aGTBoost Model*

---

### Description

`gbt.save` is an interface for storing a **agtboost** model.

### Usage

```
gbt.save(gbt_model, file)
```

### Arguments

`gbt_model` Model object or pointer to object of class ENSEMBLE  
`file` Valid file-path

### Details

The model-storage function for **agtboost**. Saves a GTB model as a txt file. Might be retrieved using `gbt.load`

**Value**

Txt file that can be loaded using `gbt.load`.

**See Also**

[gbt.load](#)

---

<code>gbt.train</code>	<i>aGTBoost Training.</i>
------------------------	---------------------------

---

**Description**

`gbt.train` is an interface for training an **agtbost** model.

**Usage**

```
gbt.train(
  y,
  x,
  learning_rate = 0.01,
  loss_function = "mse",
  nrounds = 50000,
  verbose = 0,
  gsub_compare,
  algorithm = "global_subset",
  previous_pred = NULL,
  weights = NULL,
  force_continued_learning = FALSE,
  offset = NULL,
  ...
)
```

**Arguments**

- |                            |  |
|----------------------------|--|
| <code>y</code>             | response vector for training. Must correspond to the design matrix <code>x</code> .  |
| <code>x</code>             | design matrix for training. Must be of type <code>matrix</code> .  |
| <code>learning_rate</code> | control the learning rate: scale the contribution of each tree by a factor of $0 < \text{learning\_rate} < 1$ when it is added to the current approximation. Lower value for <code>learning_rate</code> implies an increase in the number of boosting iterations: low <code>learning_rate</code> value means model more robust to overfitting but slower to compute. Default: 0.01 |
| <code>loss_function</code> | specify the learning objective (loss function). Only pre-specified loss functions are currently supported. <ul style="list-style-type: none"> <li>• mse regression with squared error loss (Default).</li> <li>• logloss logistic regression for binary classification, output score before logistic transformation.</li> </ul>  |

	<ul style="list-style-type: none"> <li>• <code>poisson</code> Poisson regression for count data using a log-link, output score before natural transformation.</li> <li>• <code>gamma:neginv</code> gamma regression using the canonical negative inverse link. Scaling independent of <math>y</math>.</li> <li>• <code>gamma:log</code> gamma regression using the log-link. Constant information parametrisation.</li> <li>• <code>negbinom</code> Negative binomial regression for count data with overdispersion. Log-link.</li> <li>• <code>count:auto</code> Chooses automatically between Poisson or negative binomial regression.</li> </ul>
<code>nrounds</code>	a just-in-case max number of boosting iterations. Default: 50000
<code>verbose</code>	Enable boosting tracing information at $i$ -th iteration? Default: 0.
<code>gsub_compare</code>	Deprecated. Boolean: Global-subset comparisons. FALSE means standard GTB, TRUE compare subset-splits with global splits (next root split). Default: TRUE.
<code>algorithm</code>	specify the algorithm used for gradient tree boosting. <ul style="list-style-type: none"> <li>• <code>vanilla</code> ordinary gradient tree boosting. Trees are optimized as if they were the last tree.</li> <li>• <code>global_subset</code> function-change to target maximized reduction in generalization loss for individual datapoints</li> </ul>
<code>previous_pred</code>	prediction vector for training. Boosted training given predictions from another model.
<code>weights</code>	weights vector for scaling contributions of individual observations. Default NULL (the unit vector).
<code>force_continued_learning</code>	Boolean: FALSE (default) stops at information stopping criterion, TRUE stops at <code>nround</code> iterations.
<code>offset</code>	add offset to the model $g(\mu) = \text{offset} + F(x)$ .
<code>...</code>	additional parameters passed. <ul style="list-style-type: none"> <li>• if <code>loss_function</code> is <code>'negbinom'</code>, dispersion must be provided in <code>...</code></li> </ul>

## Details

These are the training functions for an **agtboost**.

Explain the philosophy and the algorithm and a little math

`gbt.train` learn trees with adaptive complexity given by an information criterion, until the same (but scaled) information criterion tells the algorithm to stop. The data used for training at each boosting iteration stems from a second order Taylor expansion to the loss function, evaluated at predictions given by ensemble at the previous boosting iteration.

## Value

An object of class `ENSEMBLE` with some or all of the following elements:

- `handle` a handle (pointer) to the **agtboost** model in memory.

- initialPred a field containing the initial prediction of the ensemble.
- set\_param function for changing the parameters of the ensemble.
- train function for re-training (or from scratch) the ensemble directly on vector y and design matrix x.
- predict function for predicting observations given a design matrix
- predict2 function as above, but takes a parameter max number of boosting ensemble iterations.
- estimate\_generalization\_loss function for calculating the (approximate) optimism of the ensemble.
- get\_num\_trees function returning the number of trees in the ensemble.

```

---

predict.Rcpp\_ENSEMBLE *aGTBoost Prediction*

---

## Description

predict is an interface for predicting from a **agtboost** model.

## Usage

```
## S3 method for class 'Rcpp_ENSEMBLE'
predict(object, newdata, ...)
```

**Arguments**

object	Object or pointer to object of class ENSEMBLE
newdata	Design matrix of data to be predicted. Type <code>matrix</code>
...	additional parameters passed. Currently not in use.

**Details**

The prediction function for **agtboost**. Using the generic `predict` function in R is also possible, using the same arguments.

**Value**

For regression or binary classification, it returns a vector of length `nrows(newdata)`.
