

Package ‘rSpectral’

July 23, 2025

Type Package

Title Spectral Modularity Clustering

Version 1.0.0.10

Description Implements the network clustering algorithm described in Newman (2006) <[doi:10.1103/PhysRevE.74.036104](https://doi.org/10.1103/PhysRevE.74.036104)>. The complete iterative algorithm comprises of two steps. In the first step, the network is expressed in terms of its leading eigenvalue and eigenvector and recursively partition into two communities.

Partitioning occurs if the maximum positive eigenvalue is greater than the tolerance ($10e-5$) for the current partition, and if it results in a positive contribution to the Modularity.

Given an initial separation using the leading eigen step, 'rSpectral' then continues to maximise for the change in Modularity using a fine-tuning step - or variate thereof. The first stage here is to find the node which, when moved from one community to another, gives the maximum change in Modularity. This node's community is then fixed and we repeat the process until all nodes have been moved. The whole process is repeated from this new state until the change in the Modularity, between the new and old state, is less than the predefined tolerance.

A slight variant of the fine-tuning step, which can improve speed of the calculation, is also provided. Instead of moving each node into each community in turn, we only consider moves of neighbouring nodes, found in different communities, to the community of the current node of interest. The two steps process is repeatedly applied to each new community found, subdivided each community into two new communities, until we are unable to find any division that results in a positive change in Modularity.

rSpectral	<i>rSpectral</i>
-----------	------------------

Description

This package implements the Spectral Modularity clustering algorithm for [igraph](#) and [graphNEL](#) graphs. The algorithm was proposed in (Newman 2006) and an example of its application to the real biological network could be found in (Roy et al. 2018).

spectral_graphNEL	<i>Spectral clustering for graphNEL objects</i>
-------------------	---

Description

Spectral clustering for [graphNEL](#) objects

Usage

```
spectral_graphNEL(g, Cn_min = 1L, tol = 1e-05, names = 1L, fix_neig = 0L)
```

Arguments

<code>g</code>	graphNEL object
<code>Cn_min</code>	minimum cluster size
<code>tol</code>	tolerance
<code>names</code>	are we dealing with alphaNumeric (1) or numeric (!1) ids
<code>fix_neig</code>	whether to fix neighbouring nodes found in same community

Value

`data.frame` with node names and membership information

See Also

[spectral_igraph_membership](#)

Examples

```
library(graph)
V = letters[1:12]
g2 = randomEGraph(V, edges=20)
mem.df = spectral_graphNEL(g2)
head(mem.df)
```

`spectral_igraph_communities`*Spectral clustering for igraph objects*

Description

This function invoke `spectral_igraph_membership` to calculate clustering and convert it into `communities` object for seamless work with native `igraph` clustering functions.

Usage

```
spectral_igraph_communities(  
  g,  
  Cn_min = 1L,  
  tol = 1e-05,  
  names = 1L,  
  fix_neig = 0L  
)
```

Arguments

<code>g</code>	igraph object
<code>Cn_min</code>	minimum cluster size
<code>tol</code>	tolerance
<code>names</code>	are we dealing with alphaNumeric (1) or numeric (!1) ids
<code>fix_neig</code>	whether to fix neighbouring nodes found in same community

Value

`communities` object

Examples

```
data(karate,package='igraphdata')  
c<-spectral_igraph_communities(karate)
```

spectral_igraph_membership

Spectral clustering for igraph objects

Description

This function implements the network clustering algorithm described in (M. E. J. Newman, 2006).

Usage

```
spectral_igraph_membership(
  g,
  Cn_min = 1L,
  tol = 1e-05,
  names = 1L,
  fix_neig = 0L
)
```

Arguments

<code>g</code>	igraph object
<code>Cn_min</code>	minimum cluster size
<code>tol</code>	tolerance
<code>names</code>	are we dealing with alphaNumeric (1) or numeric (!1) ids
<code>fix_neig</code>	whether to fix neighbouring nodes found in same community

Details

The complete iterative algorithm comprises of two steps. In the first step, the network is expressed in terms of its leading eigenvalue and eigenvector and recursively partition into two communities. Partitioning occurs if the maximum positive eigenvalue is greater than the tolerance (`tol=10-5`) for the current partition, and if it results in a positive contribution to the Modularity.

Given an initial separation using the leading eigen step, the function then continues to maximise for the change in Modularity using a fine-tuning step - or variate thereof. The first stage here is to find the node which, when moved from one community to another, gives the maximum change in Modularity. This node's community is then fixed and we repeat the process until all nodes have been moved. The whole process is repeated from this new state until the change in the Modularity, between the new and old state, is less than the predefined tolerance (`tol`).

A slight variant of the fine-tuning step, which can reduce execution time by factor 2 to 5, is also provided. Instead of moving each node into each community in turn, we only consider moves of neighbouring nodes, found in different communities, to the community of the current node of interest. This variant of the node-moving algorithm effectively 'fixes' neighbouring nodes `fix_neig` in the community being considered.

The two steps process is repeatedly applied to each new community found, subdivided each community into two new communities, until we are unable to find any division that results in a positive

change in Modularity. An additional stopping criteria, based on the minimum cluster size Cn_{min} , is also provided.

Value

data.frame with node names and membership information

Examples

```
data(karate, package='igraphdata')  
df.mem<-spectral_igraph_membership(karate)
```
