Package 'unmarked'

July 22, 2025

Version 1.5.0

Date 2025-02-09

Type Package

Title Models for Data from Unmarked Animals

Depends R (>= 4.0)

Imports graphics, lattice, MASS, Matrix, methods, parallel, Rcpp (>=
0.8.0), reformulas, stats, TMB (>= 1.7.18), utils

Suggests pbapply, knitr, rmarkdown, raster, shiny, testthat, terra

Description

Fits hierarchical models of animal abundance and occurrence to data collected using survey methods such as point counts, site occupancy sampling, distance sampling, removal sampling, and double observer sampling. Parameters governing the state and observation processes can be modeled as functions of covariates. References: Kellner et al. (2023) <doi:10.1111/2041-210X.14123>, Fiske and Chandler (2011) <doi:10.18637/jss.v043.i10>.

unmarked–package	*Models for Data from Unmarked Animals*

Description

Fits hierarchical models of animal occurrence and abundance to data collected on species that may be detected imperfectly. Models include single- and multi-season site occupancy models, binomial N-mixture models, and multinomial N-mixture models. The data can arise from survey methods such as occurrence sampling, temporally replicated counts, removal sampling, double observer sampling, and distance sampling. Parameters governing the state and observation processes can be modeled as functions of covariates. General treatment of these models can be found in MacKenzie et al. (2006) and Royle and Dorazio (2008). The primary reference for the package is Fiske and Chandler (2011).

Details

Overview of Model-fitting Functions:

occu fits occurrence models with no linkage between abundance and detection (MacKenzie et al. 2002).

occuRN fits abundance models to presence/absence data by exploiting the link between detection probability and abundance (Royle and Nichols 2003).

occuFP fits occupancy models to data characterized by false negatives and false positive detections (e.g., Royle and Link [2006] and Miller et al. [2011]).

occuMulti fits multi-species occupancy model of Rota et al. [2016].

colext fits the mutli-season occupancy model of MacKenzie et al. (2003).

pcount fits N-mixture models (aka binomial mixture models) to repeated count data (Royle 2004a, Kery et al 2005).

distsamp fits the distance sampling model of Royle et al. (2004) to distance data recorded in discrete intervals.

gdistsamp fits the generalized distance sampling model described by Chandler et al. (2011) to distance data recorded in discrete intervals.

gpcount fits the generalized N-mixture model described by Chandler et al. (2011) to repeated count data collected using the robust design.

multinomPois fits the multinomial-Poisson model of Royle (2004b) to data collected using methods such as removal sampling or double observer sampling.

gmultmix fits a generalized form of the multinomial-mixture model of Royle (2004b) that allows for estimating availability and detection probability.

pcountOpen fits the open population model of Dail and Madsen (2011) to repeated count data. This is a genearlized form of the Royle (2004a) N-mixture model that includes parameters for recruitment and apparent survival.

Data: All data are passed to unmarked's estimation functions as a formal S4 class called an un-markedFrame, which has child classes for each model type. This allows metadata (eg as distance

interval cut points, measurement units, etc...) to be stored with the response and covariate data. See unmarkedFrame for a detailed description of unmarkedFrames and how to create them.

Model Specification: *unmarked*'s model-fitting functions allow specification of covariates for both the state process and the detection process. For two-level hierarchical models, (eg occu, occuRN, pcount, multinomPois, distsamp) covariates for the detection process (at the site or observation level) and the state process (at the site level) are specified with a double right-hand sided formula, in that order. Such a formula looks like

$$x1 + x2 + \ldots + x_n \; x_1 + x_2 + \ldots + x_n$$

where x_1 through x_n are additive covariates of the process of interest. Using two tildes in a single formula differs from standard R convention, but it is informative about the model being fit. The meaning of these covariates, or what they model, is full described in the help files for the individual functions and is not the same for all functions. For models with more than two processes (eg colext, gmultmix, pcountOpen), single right-hand sided formulas (only one tilde) are used to model each parameter.

Utility Functions: *unmarked* contains several utility functions for organizing data into the form required by its model-fitting functions. csvToUMF converts an appropriately formated comma-separated values (.csv) file to a list containing the components required by model-fitting functions.

backTransform-methods *Methods for Function backTransform in Package 'unmarked'*

Description

Methods for function backTransform in Package 'unmarked'. This converts from link-scale to original-scale

Usage

```
## S4 method for signature 'unmarkedFit'
backTransform(obj, type)
## S4 method for signature 'unmarkedEstimate'
backTransform(obj)
```

Arguments

obj   Object of appropriate S4 class

type   one of names(obj), eg 'state' or 'det'

Methods

obj = "unmarkedEstimate" Typically done internally

obj = "unmarkedFit" Back-transform a parameter from a fitted model. Only possible if no covariates are present. Must specify argument type as one of the values returned by names(obj).

obj = "unmarkedLinComb" Back-transform a predicted value created by linearComb. This is done internally by [predict](#) but can be done explicitly by user.

Examples

```
## Not run:

data(mallard)
mallardUMF <- unmarkedFramePCount(mallard.y, siteCovs = mallard.site,
    obsCovs = mallard.obs)

(fm <- pcount(~ 1 ~ forest, mallardUMF))    # Fit a model
backTransform(fm, type="det")            # This works because there are no detection covariates
#backTransform(fm, type="state")         # This doesn't work because covariates are present
lc <- linearComb(fm, c(1, 0), type="state") # Estimate abundance on the log scale when forest=0
backTransform(lc)                        # Abundance on the original scale

## End(Not run)
```

---

birds   *BBS Point Count and Occurrence Data from 2 Bird Species*

Description

Data frames for 2 species from the breeding bird survey (BBS). Each data frame has a row for each
site and columns for each sampling event. There is a point count and occurrence–designated by
`.bin`– version for each species.

Usage

```
data(birds)
```

Format

`catbird` A data frame of point count observations for the catbird.

`catbird.bin` A data frame of occurrence observations for the catbird.

`woodthrush` A data frame of point count observations for the wood thrush.

`woodthrush.bin` A data frame of point count observations for the wood thrush.

Source

Royle J. N-mixture models for estimating population size from spatially replicated counts. Biomet-
rics. 2004. 60(1):108–115.

Examples

```
data(birds)
```

---

bup   *Extract Best Unbiased Predictors (BUPs) of latent variables from*
                             ranef *output*

Description

Extract Best Unbiased Predictors (BUPs) of latent variables such as occupancy or abundance from
a `unmarkedRanef` object produced by the `ranef` function. Either the posterior mean or median can
be requested.

Usage

```
## S4 method for signature 'unmarkedRanef'
bup(object, stat = c("mean", "mode"), ...)
```

Arguments

object	A unmarkedRanef object, the output of a call to ranef.
stat	The statistic to calculate from the posterior, either mean or mode.
...	Other arguments, currently ignored

Value

A vector of length M for single-season models, where M is the number of sites. A matrix MxT for multi-season models, where T is the number of primary periods. Values in the vector or matrix are the BUPs (occupancy or abundance states).

See Also

[ranef](#), [unmarkedRanef-class](#)

---

coef-methods   *Methods for Function coef in Package 'unmarked'*

Description

Extract coefficients

Usage

```
## S4 method for signature 'unmarkedFit'
coef(object, type, altNames = TRUE, fixedOnly=TRUE)
## S4 method for signature 'unmarkedEstimate'
coef(object, altNames = TRUE, fixedOnly=TRUE, ...)
## S4 method for signature 'linCombOrBackTrans'
coef(object)
```

Arguments

object	Object of appropriate S4 class
type	Either 'state' or 'det'
altNames	Return specific names for parameter estimates?
fixedOnly	Return only fixed effect parameters?
...	Further arguments. Not currently used

Value

A named numeric vector of parameter estimates.

Methods

object = "linCombOrBackTrans" Object from linearComb

object = "unmarkedEstimate" unmarkedEstimate object

object = "unmarkedFit" Fitted model

---

colext   *Fit the dynamic occupancy model of MacKenzie et. al (2003)*

Description

Estimate parameters of the colonization-extinction model, including covariate-dependent rates and detection process.

Usage

```
colext(psiformula= ~1, gammaformula =  ~ 1, epsilonformula = ~ 1,
    pformula = ~ 1, data, starts, method="BFGS", se=TRUE, ...)
```

Arguments

psiformula	Right-hand sided formula for the initial probability of occupancy at each site.
gammaformula	Right-hand sided formula for colonization probability.
epsilonformula	Right-hand sided formula for extinction probability.
pformula	Right-hand sided formula for detection probability.
data	unmarkedMultFrame object that supplies the data (see [unmarkedMultFrame](#)).
starts	optionally, initial values for parameters in the optimization.
method	Optimization method used by [optim](#).
se	logical specifying whether or not to compute standard errors.
...	Additional arguments to optim, such as lower and upper bounds

Details

This function fits the colonization-extinction model of MacKenzie et al (2003). The colonization and extinction rates can be modeled with covariates that vary yearly at each site using a logit link. These covariates are supplied by special unmarkedMultFrame yearlySiteCovs slot. These parameters are specified using the gammaformula and epsilonformula arguments. The initial probability of occupancy is modeled by covariates specified in the psiformula.

The conditional detection rate can also be modeled as a function of covariates that vary at the secondary sampling period (ie., repeat visits). These covariates are specified by the first part of the formula argument and the data is supplied via the usual obsCovs slot.

The projected and smoothed trajectories (Weir et al 2009) can be obtained from the smoothed.mean and projected.mean slots (see examples).

Value

unmarkedFitColExt object describing model fit.

computeMPLElambda   *Compute the penalty weight for the MPLE penalized likelihood method*

Description

This function computes the weight for the MPLE penalty of Moreno & Lele (2010).

Usage

```
computeMPLElambda(formula, data, knownOcc=numeric(0), starts,
method="BFGS",engine=c("C", "R"))
```

Arguments

formula	Double right-hand side formula describing covariates of detection and occupancy in that order.
data	An [unmarkedFrameOccu](#) object
knownOcc	Vector of sites that are known to be occupied. These should be supplied as row numbers of the y matrix, eg, c(3,8) if sites 3 and 8 were known to be occupied a priori.
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
engine	Either "C" or "R" to use fast C++ code or native R code during the optimization.

Details

See [occuPEN](#) for details and examples.

Value

The computed lambda.

Author(s)

Rebecca A. Hutchinson

confint-methods   *Methods for Function confint in Package 'unmarked'*

Description

Methods for function `confint` in Package 'unmarked'

Usage

```
## S4 method for signature 'unmarkedBackTrans'
confint(object, parm, level)
## S4 method for signature 'unmarkedEstimate'
confint(object, parm, level)
## S4 method for signature 'unmarkedLinComb'
confint(object, parm, level)
## S4 method for signature 'unmarkedFit'
confint(object, parm, level, type, method)
```

Arguments

object	Object of appropriate S4 class
parm	Name of parameter(s) of interest
level	Level of confidence
type	Either "state" or "det"
method	Either "normal" or "profile"

Value

A vector of lower and upper confidence intervals. These are asymtotic unless method='profile' is used on unmarkedFit objects in which case they are profile likelihood intervals.

crossVal *Cross-validation methods for fitted* unmarked *models and fit lists*

Description

Test predictive accuracy of fitted models using several cross-validation approaches. The dataset is divided by site only into folds or testing and training datasets (i.e., encounter histories within sites are never split up).

Usage

```
## S4 method for signature 'unmarkedFit'
crossVal(
  object, method=c("Kfold","holdout","leaveOneOut"),
  folds=10, holdoutPct=0.25, statistic=RMSE_MAE, parallel=FALSE, ncores, ...)
## S4 method for signature 'unmarkedFitList'
crossVal(
  object, method=c("Kfold","holdout","leaveOneOut"),
  folds=10, holdoutPct=0.25, statistic=RMSE_MAE, parallel=FALSE, ncores,
  sort = c("none", "increasing", "decreasing"), ...)
```

Arguments

object	A fitted model inheriting class unmarkedFit or a list of fitted models with class unmarkedFitList
method	Cross validation method to use as string. Valid options are "Kfold", "holdout", or "leaveOneOut"
folds	Number of folds to use for k-fold cross validation
holdoutPct	Proportion of dataset (value between 0-1) to use as the "holdout" or "test" set, for the holdout method
statistic	Function that calculates statistics for each fold. The function must take an unmarkedFit object as the first argument and return a named numeric vector with statistic value(s). The default function RMSE_MAE returns root-mean-square error and mean absolute error. See unmarked:::RMSE_MAE for an example of correct statistic function structure.
parallel	If TRUE, run folds in parallel. This may speed up cross-validation if the unmarked model takes a long time to fit or you have a large number of sites and are using leave-one-out cross-validation.
ncores	Number of parallel cores to use.
sort	If doing cross-validation on a fitList, you can optionally sort the resulting table(s) of statistic values for each model.
...	Other arguments passed to the statistic function.

Value

unmarkedCrossVal or unmarkedCrossValList object containing calculated statistic values for each fold.

cruz   *Landscape data for Santa Cruz Island*

Description

Spatially-referenced elevation, forest cover, and vegetation data for Santa Cruz Island.

Usage

```
data(cruz)
```

Format

A data frame with 2787 observations on the following 5 variables.

x Easting (meters)

y Northing (meters)

elevation a numeric vector, FEET (multiply by 0.3048 to convert to meters)

forest a numeric vector, proportion cover

chaparral a numeric vector, proportion cover

Details

The resolution is 300x300 meters.

The Coordinate system is EPSG number 26911

NAD_1983_UTM_Zone_11N Projection: Transverse_Mercator False_Easting: 500000.000000 False_Northing: 0.000000 Central_Meridian: -117.000000 Scale_Factor: 0.999600 Latitude_Of_Origin: 0.000000 Linear Unit: Meter GCS_North_American_1983 Datum: D_North_American_1983

csvToUMF   *Convert .CSV File to an unmarkedFrame*

Description

This function converts an appropriately formated comma-separated values file (.csv) to a format usable by *unmarked*'s fitting functions (see *Details*).

Usage

```
csvToUMF(filename, long=FALSE, type, species, ...)
```

Arguments

filename	string describing filename of file to read in
long	FALSE if file is in long format or TRUE if file is in long format (see *Details*)
species	if data is in long format with multiple species, then this can specify a particular species to extract if there is a column named "species".
type	specific type of unmarkedFrame.
...	further arguments to be passed to the unmarkedFrame constructor.

Details

This function provides a quick way to take a .csv file with headers named as described below and provides the data required and returns of data in the format required by the model-fitting functions in [unmarked](). The .csv file can be in one of 2 formats: long or wide. See the first 2 lines of the *examples* for what these formats look like.

The .csv file is formatted as follows:

- col 1 is site labels.
- if data is in long format, col 2 is date of observation.
- next J columns are the observations (y) - counts or 0/1's.
- next is a series of columns for the site variables (one column per variable). The column header is the variable name.
- next is a series of columns for the observation-level variables. These are in sets of J columns for each variable, e.g., var1-1 var1-2 var1-3 var2-1 var2-2 var2-3, etc. The column header of the first variable in each group must indicate the variable name.

Value

an unmarkedFrame object

Author(s)

Ian Fiske <ianfiske@gmail.com>

Examples

```
# examine a correctly formatted long .csv
head(read.csv(system.file("csv","frog2001pcru.csv", package="unmarked")))

# examine a correctly formatted wide .csv
head(read.csv(system.file("csv","widewt.csv", package="unmarked")))

# convert them!

                 long = FALSE, type = "unmarkedFrameOccu")
```

---

detFuns	*Distance-sampling detection functions and associated density functions*

Description

These functions represent the currently available detection functions used for modeling line and point transect data with distsamp. Detection functions begin with "g", and density functions begin with a "d".

Usage

```
gxhn(x, sigma)
gxexp(x, rate)
gxhaz(x, shape, scale)

dxhn(x, sigma)
dxexp(x, rate)
dxhaz(x, shape, scale)
drhn(r, sigma)
drexp(r, rate)
drhaz(r, shape, scale)
```

Arguments

x	Perpendicular distance
r	Radial distance
sigma	Shape parameter of half-normal detection function

rate	Shape parameter of negative-exponential detection function
shape	Shape parameter of hazard-rate detection function
scale	Scale parameter of hazard-rate detection function

See Also

distsamp for example of using these for plotting detection function

Examples

```
# Detection probabilities at 25m for range of half-normal sigma values.
round(gxhn(25, 10:15), 2)

# Plot negative exponential distributions
plot(function(x) gxexp(x, rate=10), 0, 50, xlab="distance",
    ylab="Detection probability")
plot(function(x) gxexp(x, rate=20), 0, 50, add=TRUE, lty=2)
plot(function(x) gxexp(x, rate=30), 0, 50, add=TRUE, lty=3)

# Plot half-normal probability density functions for line- and point-transects
par(mfrow=c(2, 1))
plot(function(x) dxhn(x, 20), 0, 50, xlab="distance",
    ylab="Probability density", main="Line-transect")
plot(function(x) drhn(x, 20), 0, 50, xlab="distance",
    ylab="Probability density", main="Point-transect")
```

---

distsamp   *Fit the hierarchical distance sampling model of Royle et al. (2004)*

Description

Fit the hierarchical distance sampling model of Royle et al. (2004) to line or point transect data recorded in discrete distance intervals.

Usage

```
distsamp(formula, data, keyfun=c("halfnorm", "exp",
  "hazard", "uniform"), output=c("density", "abund"),
  unitsOut=c("ha", "kmsq"), starts, method="BFGS", se=TRUE,
  engine=c("C", "R", "TMB"), rel.tol=0.001, ...)
```

Arguments

formula	Double right-hand formula describing detection covariates followed by abundance covariates. ~1 ~1 would be a null model.
data	object of class unmarkedFrameDS, containing response matrix, covariates, distance interval cut points, survey type ("line" or "point"), transect lengths (for survey = "line"), and units ("m" or "km") for cut points and transect lengths. See example for set up.

keyfun	One of the following detection functions: "halfnorm", "hazard", "exp", or "uniform." See details.
output	Model either "density" or "abund"
unitsOut	Units of density. Either "ha" or "kmsq" for hectares and square kilometers, respectively.
starts	Vector of starting values for parameters.
method	Optimization method used by `optim`.
se	logical specifying whether or not to compute standard errors.
engine	Use code written in C++ or R
rel.tol	Requested relative accuracy of the integral, see `integrate`
...	Additional arguments to optim, such as lower and upper bounds

Details

Unlike conventional distance sampling, which uses the 'conditional on detection' likelihood formulation, this model is based upon the unconditional likelihood and allows for modeling both abundance and detection function parameters.

The latent transect-level abundance distribution $f(N|\theta)$ assumed to be Poisson with mean λ (but see `gdistsamp` for alternatives).

The detection process is modeled as multinomial: $y_{ij} \sim Multinomial(N_i, \pi_{ij})$, where π_{ij} is the multinomial cell probability for transect i in distance class j. These are computed based upon a detection function $g(x|\sigma)$, such as the half-normal, negative exponential, or hazard rate.

Parameters λ and σ can be vectors affected by transect-specific covariates using the log link.

Value

unmarkedFitDS object (child class of `unmarkedFit-class`) describing the model fit.

Note

You cannot use obsCovs.

distsampOpen   *Open population model for distance sampling data*

Description

Fit the model of Dail and Madsen (2011) and Hostetler and Chandler (2015) with a distance sampling observation model (Sollmann et al. 2015).

Usage

```
distsampOpen(lambdaformula, gammaformula, omegaformula, pformula,
    data, keyfun=c("halfnorm", "exp", "hazard", "uniform"),
    output=c("abund", "density"), unitsOut=c("ha", "kmsq"),
    mixture=c("P", "NB", "ZIP"), K,
    dynamics=c("constant", "autoreg", "notrend", "trend", "ricker", "gompertz"),
    fix=c("none", "gamma", "omega"), immigration=FALSE, iotaformula = ~1,
    starts, method="BFGS", se=TRUE, ...)
```

Arguments

lambdaformula	Right-hand sided formula for initial abundance
gammaformula	Right-hand sided formula for recruitment rate (when dynamics is "constant", "autoreg", or "notrend") or population growth rate (when dynamics is "trend", "ricker", or "gompertz")
omegaformula	Right-hand sided formula for apparent survival probability (when dynamics is "constant", "autoreg", or "notrend") or equilibrium abundance (when dynamics is "ricker" or "gompertz")
pformula	A right-hand side formula describing the detection function covariates
data	An object of class [unmarkedFrameDSO]
keyfun	One of the following detection functions: "halfnorm", "hazard", "exp", or "uniform"
output	Model either "density" or "abund"
unitsOut	Units of density. Either "ha" or "kmsq" for hectares and square kilometers, respectively
mixture	String specifying mixture: "P", "NB", or "ZIP" for the Poisson, negative binomial, or zero-inflated Poisson distributions respectively
K	Integer defining upper bound of discrete integration. This should be higher than the maximum observed count and high enough that it does not affect the parameter estimates. However, the higher the value the slower the computation
dynamics	Character string describing the type of population dynamics. "constant" indicates that there is no relationship between omega and gamma. "autoreg" is an auto-regressive model in which recruitment is modeled as gamma*N[i,t-1]. "notrend" model gamma as lambda*(1-omega) such that there is no temporal trend. "trend" is a model for exponential growth, N[i,t] = N[i,t-1]*gamma, where gamma in this case is finite rate of increase (normally referred to as lambda). "ricker" and "gompertz" are models for density-dependent population growth. "ricker" is the Ricker-logistic model, N[i,t] = N[i,t-1]*exp(gamma*(1-N[i,t-1]/omega)), where gamma is the maximum instantaneous population growth

rate (normally referred to as r) and omega is the equilibrium abundance (normally referred to as K). "gompertz" is a modified version of the Gompertz-logistic model, N[i,t] = N[i,t-1]*exp(gamma*(1-log(N[i,t-1]+1)/log(omega+1))), where the interpretations of gamma and omega are similar to in the Ricker model

`fix`	If "omega", omega is fixed at 1. If "gamma", gamma is fixed at 0
`immigration`	Logical specifying whether or not to include an immigration term (iota) in population dynamics
`iotaformula`	Right-hand sided formula for average number of immigrants to a site per time step
`starts`	Vector of starting values
`method`	Optimization method used by optim
`se`	Logical specifying whether or not to compute standard errors
`...`	Additional arguments to optim, such as lower and upper bounds

Details

These models generalize distance sampling models (Buckland et al. 2001) by relaxing the closure assumption (Dail and Madsen 2011, Hostetler and Chandler 2015, Sollmann et al. 2015).

The models include two or three additional parameters: gamma, either the recruitment rate (births and immigrations), the finite rate of increase, or the maximum instantaneous rate of increase; omega, either the apparent survival rate (deaths and emigrations) or the equilibrium abundance (carrying capacity); and iota, the number of immigrants per site and year. Estimates of population size at each time period can be derived from these parameters, and thus so can trend estimates. Or, trend can be estimated directly using dynamics="trend".

When immigration is set to FALSE (the default), iota is not modeled. When immigration is set to TRUE and dynamics is set to "autoreg", the model will separately estimate birth rate (gamma) and number of immigrants (iota). When immigration is set to TRUE and dynamics is set to "trend", "ricker", or "gompertz", the model will separately estimate local contributions to population growth (gamma and omega) and number of immigrants (iota).

The latent abundance distribution, $f(N|\theta)$ can be set as a Poisson, negative binomial, or zero-inflated Poisson random variable, depending on the setting of the `mixture` argument, `mixture = "P"`, `mixture = "NB"`, `mixture = "ZIP"` respectively. For the first two distributions, the mean of N_i is λ_i. If $N_i \sim NB$, then an additional parameter, α, describes dispersion (lower α implies higher variance). For the ZIP distribution, the mean is $\lambda_i(1-\psi)$, where psi is the zero-inflation parameter.

For "constant", "autoreg", or "notrend" dynamics, the latent abundance state following the initial sampling period arises from a Markovian process in which survivors are modeled as $S_{it} \sim Binomial(N_{it-1}, \omega_{it})$, and recruits follow $G_{it} \sim Poisson(\gamma_{it})$. Alternative population dynamics can be specified using the `dynamics` and `immigration` arguments.

λ_i, γ_{it}, and ι_{it} are modeled using the the log link. p_{ijt} is modeled using the logit link. ω_{it} is either modeled using the logit link (for "constant", "autoreg", or "notrend" dynamics) or the log link (for "ricker" or "gompertz" dynamics). For "trend" dynamics, ω_{it} is not modeled.

For the distance sampling detection process, half-normal ("halfnorm"), exponential ("exp"), hazard ("hazard"), and uniform ("uniform") key functions are available.

Value

An object of class unmarkedFitDSO

Warning

This function can be extremely slow, especially if there are covariates of gamma or omega. Consider testing the timing on a small subset of the data, perhaps with se=FALSE. Finding the lowest value of K that does not affect estimates will also help with speed.

Note

When gamma or omega are modeled using year-specific covariates, the covariate data for the final year will be ignored; however, they must be supplied.

If the time gap between primary periods is not constant, an M by T matrix of integers should be supplied to [unmarkedFrameDSO](#) using the primaryPeriod argument.

Secondary sampling periods are optional, but can greatly improve the precision of the estimates.

Optimization may fail if the initial value of the intercept for the detection parameter (sigma) is too small or large relative to transect width. By default, this parameter is initialized at log(average band width). You may have to adjust this starting value.

fitList   *Create a list of fitted* unmarked *models*

Description

Organize models for model selection or model-averaged prediction.

Usage

```
fitList(..., fits, autoNames=c("object", "formula"))
```

Arguments

`...`	Fitted models. Preferrably named.
`fits`	An alternative way of providing the models. A (preferrably named) list of fitted models.
`autoNames`	Option to change the names unmarked assigns to models if you don't name them yourself. If `autoNames="object"`, models in the `fitList` will be named based on their R object names. If `autoNames="formula"`, the models will instead be named based on their formulas. This is not possible for some model types.

Note

Two requirements exist to conduct AIC-based model-selection and model-averaging in unmarked. First, the data objects (ie, unmarkedFrames) must be identical among fitted models. Second, the response matrix must be identical among fitted models after missing values have been removed. This means that if a response value was removed in one model due to missingness, it needs to be removed from all models.

fm2 <- distsamp(~ area ~1, ltUMF)
fm3 <- distsamp( ~ 1 ~area, ltUMF)

## Two methods of creating an unmarkedFitList using fitList()

# Method 1
fmList <- fitList(Null=fm1, .area=fm2, area.=fm3)

# Method 2. Note that the arugment name "fits" must be included in call.
models <- list(Null=fm1, .area=fm2, area.=fm3)
fmList <- fitList(fits = models)

# Extract coefficients and standard errors
coef(fmList)
SE(fmList)

# Model-averaged prediction
predict(fmList, type="state")

# Model selection
modSel(fmList, nullmod="Null")
```

---

fitted   *Calculate fitted (expected) values from a model*

Description

Calculates expected values from a model. The approach varies based on the model type but is usually the product of the state and detection parameters.

Usage

```
## S4 method for signature 'unmarkedFit'
fitted(object, ...)
```

Arguments

object	A unmarkedFit object
...	Other arguments, currently ignored.

Value

In most cases, fitted returns a matrix of expected values with the same dimensions as the y matrix (M x J or M x JT). For some models with multiple observation processes or multiple species, such as gdistremoval or occuMulti, the output may be a named list of matrices.

---

formatDistData   *Bin distance data*

Description

Convert individual-level distance data to the transect-level format required by distsamp or gdistsamp

Usage

```
formatDistData(distData, distCol, transectNameCol, dist.breaks,
                   occasionCol, effortMatrix)
```

Arguments

distData   data.frame where each row is a detected individual. Must have at least 2 columns. One for distances and the other for transect names.

distCol   character, name of the column in distData that contains the distances. The distances should be numeric.

transectNameCol

                  character, column name containing transect names. The transect column should be a factor.

dist.breaks   numeric vector of distance interval cutpoints. Length must equal J+1.

occasionCol   optional character. If transects were visited more than once, this can be used to format data for gdistsamp. It is the name of the column in distData that contains the occasion numbers. The occasion column should be a factor.

effortMatrix   optional matrix of 1 and 0s that is M * T in size and will allow for the insertion of NAs where the matrix = 0, indicating that a survey was not completed. When not supplied a matrix of all 1s is created since it is assumed all surveys were completed.

Details

This function creates a site (M) by distance interval (J) response matrix from a data.frame containing the detection distances for each individual and the transect names. Alternatively, if each transect was surveyed T times, the resulting matrix is M x JT, which is the format required by gdistsamp, see unmarkedFrameGDS.

Value

An M x J or M x JT matrix containing the binned distance data. Transect names will become rownames and colnames will describe the distance intervals.

Note

It is important that the factor containing transect names includes levels for all the transects surveyed, not just those with >=1 detection. Likewise, if transects were visited more than once, the factor containing the occasion numbers should include levels for all occasions. See the example for how to add levels to a factor.

See Also

[distsamp](), [unmarkedFrame]()

Examples

```
# Create a data.frame containing distances of animals detected
# along 4 transects.
dat <- data.frame(transect=gl(4,5, labels=letters[1:4]),
                  distance=rpois(20, 10))
dat

# Look at your transect names.
levels(dat$transect)

# Suppose that you also surveyed a transect named "e" where no animals were
# detected. You must add it to the levels of dat$transect
levels(dat$transect) <- c(levels(dat$transect), "e")
levels(dat$transect)

# Distance cut points defining distance intervals
cp <- c(0, 8, 10, 12, 14, 18)

# Create formated response matrix
yDat <- formatDistData(dat, "distance", "transect", cp)
yDat

# Now you could merge yDat with transect-level covariates and
# then use unmarkedFrameDS to prepare data for distsamp

## Example for data from multiple occasions

dat2 <- data.frame(distance=1:100, site=gl(5, 20),
                   visit=factor(rep(1:4, each=5)))
cutpt <- seq(0, 100, by=25)
y2 <- formatDistData(dat2, "distance", "site", cutpt, "visit")
umf <- unmarkedFrameGDS(y=y2, numPrimary=4, survey="point",
                        dist.breaks=cutpt, unitsIn="m")
 ## Example for datda from multiple occasions with effortMatrix

 dat3 <-  data.frame(distance=1:100, site=gl(5, 20), visit=factor(rep(1:4, each=5)))
 cutpt <- seq(0, 100, by=25)

 effortMatrix <- matrix(ncol=4, nrow=5, rbinom(20,1,0.8))

 y3 <- formatDistData(dat2, "distance", "site", cutpt, "visit", effortMatrix)
```

---

formatMult   *Create unmarkedMultFrame from Long Format Data Frame*

Description

This convenience function converts multi-year data in long format to unmarkedMultFrame Object. See Details for more information.

Usage

```
formatMult(df.in)
```

Arguments

df.in   a data.frame appropriately formatted (see Details).

Details

`df.in` is a data frame with columns formatted as follows:

Column 1 = year number
Column 2 = site name or number
Column 3 = julian date or chronological sample number during year
Column 4 = observations (y)
Column 5 – Final Column = covariates

Note that if the data is already in wide format, it may be easier to create an unmarkedMultFrame object directly with a call to [unmarkedMultFrame](#).

Value

unmarkedMultFrame object

---

formatWideLong   *Convert between wide and long data formats.*

Description

Convert a data.frame between wide and long formats.

Usage

```
formatWide(dfin, sep = ".", obsToY, type, ...)
formatLong(dfin, species = NULL, type, ...)
```

Arguments

dfin   A data.frame to be reformatted.
sep   A seperator of column names in wide format.
obsToY   Optional matrix specifying relationship between covariate column structure and response matrix structure.
type   Type of unmarkedFrame to create?
species   Character name of species response column
...   Further arguments to the unmarkedFrame* constructor functions

Details

Note that not all possible unmarkedFrame* classes have been tested with these functions. Multinomial data sets (e.g., removal, double-observer, capture-recapture) are almost certainly easier to enter directly to the constructor function and are not supported by formatLong or formatWide.

In order for these functions to work, the columns of dfin need to be in the correct order. formatLong requires that the columns are in the following scheme:

1. site name or number.
2. date or observation number.
3. response variable (detections, counts, etc).
4. The remaining columns are observation-level covariates.

formatWide requires particular names for the columns. The column order for formatWide is

1. (optional) site name, named "site".
2. response, named "y.1", "y.2", ..., "y.J".
3. columns of site-level covariates, each with a relevant name per column.
4. groups of columns of observation-level covariates, each group having the name form "someObsCov.1", "someObsCov.2", ..., "someObsCov.J".

Value

A data.frame

csvToUMF

---

frogs   *2001 Delaware North American Amphibian Monitoring Program Data*

Description

frogs contains NAAMP data for Pseudacris feriarum (pfer) and Pseudacris crucifer (pcru) in 2001.

Usage

```
data(frogs)
```

Format

pcru.y matrix of observed calling indices for pcru

pcru.bin matrix of detections for pcru

pcru.data array of covariates measured at the observation-level for pcru

pfer.y matrix of observed calling indices for pfer

pfer.bin matrix of detections for pfer

pfer.data array of covariates measured at the observation-level for pfer

Details

The rows of pcru.y, pcru.bin, pfer.y, and pfer.bin correspond to sites and columns correspond to
visits to each site. The first 2 dimensions of pfer.data and pcru.data are matrices of covariates that
correspond to the observation matrices (sites × observation), with the 3rd dimension corresponding
to separate covariates.

---

gdistremoval	*Fit the combined distance and removal model of Amundson et al. (2014).*

Description

Fit the model of Amundson et al. (2014) to point count datasets containing both distance and time
of observation data. The Amundson et al. (2014) model is extended to account for temporary emi-
gration by estimating an additional availability probability if multiple counts at a site are available.
Abundance can be modeled as a Poisson, negative binomial, or Zero-inflated Poisson. Multiple
distance sampling key functions are also available.

Usage

```
gdistremoval(lambdaformula=~1, phiformula=~1, removalformula=~1,
  distanceformula=~1, data, keyfun=c("halfnorm", "exp", "hazard", "uniform"),
 output=c("abund", "density"), unitsOut=c("ha", "kmsq"), mixture=c('P', 'NB', 'ZIP'),
 K, starts, method = "BFGS", se = TRUE, engine=c("C","TMB"), threads=1, ...)
```

Arguments

lambdaformula   A right-hand side formula describing the abundance covariates

phiformula   A right-hand side formula describing the availability covariates

removalformula   A right-hand side formula describing removal probability covariates

distanceformula

                A right-hand side formula describing the detection function covariates

data	An object of class unmarkedFrameGDR
keyfun	One of the following detection functions: "halfnorm", "hazard", "exp", or "uniform"
output	Model either "abund" or "density"
unitsOut	Units of density. Either "ha" or "kmsq" for hectares and square kilometers, respectively
mixture	Either "P", "NB", or "ZIP" for the Poisson, negative binomial, and Zero-inflated Poisson models of abundance
K	An integer value specifying the upper bound used in the integration
starts	A numeric vector of starting values for the model parameters
method	Optimization method used by [optim](#)
se	logical specifying whether or not to compute standard errors
engine	Either "C" to use C++ code or "TMB" to use TMB for optimization
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled
...	Additional arguments to optim, such as lower and upper bounds

Value

An object of class unmarkedFitGDR

gdistsamp   *Fit the generalized distance sampling model of Chandler et al. (2011).*

Description

Extends the distance sampling model of Royle et al. (2004) to estimate the probability of being available for detection. Also allows abundance to be modeled using the negative binomial and zero-inflated Poisson distributions.

Usage

```
gdistsamp(lambdaformula, phiformula, pformula, data, keyfun =
c("halfnorm", "exp", "hazard", "uniform"), output = c("abund",
"density"), unitsOut = c("ha", "kmsq"), mixture = c("P", "NB", "ZIP"), K,
starts, method = "BFGS", se = TRUE, engine=c("C","R"), rel.tol=1e-4, threads=1, ...)
```

Arguments

lambdaformula	A right-hand side formula describing the abundance covariates.
phiformula	A right-hand side formula describing the availability covariates.
pformula	A right-hand side formula describing the detection function covariates.
data	An object of class unmarkedFrameGDS
keyfun	One of the following detection functions: "halfnorm", "hazard", "exp", or "uniform." See details.
output	Model either "density" or "abund"
unitsOut	Units of density. Either "ha" or "kmsq" for hectares and square kilometers, respectively.
mixture	Either "P", "NB", or "ZIP" for the Poisson, negative binomial, or zero-inflated Poisson models of abundance.
K	An integer value specifying the upper bound used in the integration.
starts	A numeric vector of starting values for the model parameters.
method	Optimization method used by [optim](#).
se	logical specifying whether or not to compute standard errors.
engine	Either "C" to use fast C++ code or "R" to use native R code during the optimization.
rel.tol	relative accuracy for the integration of the detection function. See [integrate](#). You might try adjusting this if you get an error message related to the integral. Alternatively, try providing different starting values.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

Extends the model of Royle et al. (2004) by estimating the probability of being available for detection ϕ. To estimate this additional parameter, replicate distance sampling data must be collected at each transect. Thus the data are collected at i = 1, 2, ..., R transects on t = 1, 2, ..., T occassions. As with the model of Royle et al. (2004), the detections must be binned into distance classes. These data must be formatted in a matrix with R rows, and JT columns where J is the number of distance classses. See `unmarkedFrameGDS` for more information about data formatting.

The definition of availability depends on the context. The model is

$$M_i \sim \text{Pois}(\lambda)$$

$$N_{i,t} \sim \text{Bin}(M_i, \phi)$$

$$y_{i,1,t}, \ldots, y_{i,J,t} \sim \text{Multinomial}(N_{i,t}, \pi_{i,1,t}, \ldots, \pi_{i,J,t})$$

If there is no movement, then M_i is local abundance, and $N_{i,t}$ is the number of individuals that are available to be detected. In this case, $\phi = g_0$. Animals might be missed on the transect line because they are difficult to see or detected. This relaxes the assumption of conventional distance sampling that $g_0 = 1$.

However, when there is movement in the form of temporary emigration, local abundance is $N_{i,t}$; it's the fraction of M_i that are on the plot at time t. In this case, ϕ is the temporary emigration parameter, and we need to assume that $g_0 = 1$ in order to interpret $N_{i,t}$ as local abundance. See Chandler et al. (2011) for an analysis of the model under this form of temporary emigration.

If there is movement and $g_0 < 1$ then it isn't possible to estimate local abundance at time t. In this case, M_i would be the total number of individuals that ever use plot i (the super-population), and $N_{i,t}$ would be the number available to be detected at time t. Since a fraction of the unavailable individuals could be off the plot, and another fraction could be on the plot, it isn't possible to infer local abundance and density during occasion t.

Value

An object of class unmarkedFitGDS.

Note

If you aren't interested in estimating ϕ, but you want to use the negative binomial or ZIP distributions, set numPrimary=1 when formatting the data.

Note

You cannot use obsCovs, but you can use yearlySiteCovs (a confusing name since this model isn't for multi-year data. It's just a hold-over from the colext methods of formatting data upon which it is based.)

gmultmix   *Generalized multinomial N-mixture model*

Description

A three level hierarchical model for designs involving repeated counts that yield multinomial outcomes. Possible data collection methods include repeated removal sampling and double observer sampling. The three model parameters are abundance, availability, and detection probability.

Usage

```
gmultmix(lambdaformula, phiformula, pformula, data, mixture = c("P", "NB", "ZIP"), K,
         starts, method = "BFGS", se = TRUE, engine=c("C","R"), threads=1, ...)
```

Arguments

lambdaformula	Righthand side (RHS) formula describing abundance covariates
phiformula	RHS formula describing availability covariates
pformula	RHS formula describing detection covariates
data	An object of class unmarkedFrameGMM
mixture	Either "P", "NB", or "ZIP" for the Poisson, negative binomial, or zero-inflated Poisson models of abundance
K	The upper bound of integration
starts	Starting values
method	Optimization method used by [optim](#)
se	Logical. Should standard errors be calculated?
engine	Either "C" to use fast C++ code or "R" to use native R code during the optimization.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

The latent transect-level super-population abundance distribution $f(M|\theta)$ can be set as a Poisson, negative binomial, or zero-inflated Poisson random variable, depending on the setting of the mixture argument. mixture = "P", mixture = "NB", and mixture = "ZIP" select the Poisson, negative binomial, and zero-inflated Poisson distributions respectively. The mean of M_i is λ_i. If $M_i \sim NB$, then an additional parameter, α, describes dispersion (lower α implies higher variance). If $M_i \sim ZIP$, then an additional zero-inflation parameter ψ is estimated.

The number of individuals available for detection at time j is a modeled as binomial: $N_{ij} \sim Binomial(M_i, \phi_{\mathbf{ij}})$.

The detection process is modeled as multinomial: $\mathbf{y_{it}} \sim Multinomial(N_{it}, \pi_{it})$, where π_{ijt} is the multinomial cell probability for plot i at time t on occasion j.

Cell probabilities are computed via a user-defined function related to the sampling design. Alternatively, the default functions removalPiFun or doublePiFun can be used for equal-interval removal sampling or double observer sampling. Note that the function for computing cell probabilites is specified when setting up the data using unmarkedFrameGMM.

Parameters λ, ϕ and p can be modeled as linear functions of covariates using the log, logit and logit links respectively.

Value

An object of class unmarkedFitGMM.

Note

In the case where availability for detection is due to random temporary emigration, population density at time j, D(i,j), can be estimated by N(i,j)/plotArea.

This model is also applicable to sampling designs in which the local population size is closed during the J repeated counts, and availability is related to factors such as the probability of vocalizing. In this case, density can be estimated by M(i)/plotArea.

If availability is a function of both temporary emigration and other processess such as song rate, then density cannot be directly estimated, but inference about the super-population size, M(i), is possible.

Three types of covariates can be supplied, site-level, site-by-year-level, and observation-level. These must be formatted correctly when organizing the data with unmarkedFrameGPC

goccu   *Fit the multi-scale occupancy model of Nichols et al. (2008)*

Description

Fit multi-scale occupancy models as described in Nichols et al. (2008) to repeated presence-absence data collected using the robust design. This model allows for inference about occupancy, availability, and detection probability.

Usage

```
goccu(psiformula, phiformula, pformula, data, linkPsi = c("logit", "cloglog"),
      starts, method = "BFGS", se = TRUE, ...)
```

Arguments

psiformula	Right-hand sided formula describing occupancy covariates
phiformula	Right-hand sided formula describing availability covariates
pformula	Right-hand sided formula for detection probability covariates
data	An object of class unmarkedFrameGOccu or unmarkedMultFrame
linkPsi	Link function for the occupancy model. Options are "logit" for the standard occupancy model or "cloglog" for the complimentary log-log link, which relates occupancy to site-level abundance.
starts	Starting values
method	Optimization method used by optim
se	Logical. Should standard errors be calculated?
...	Additional arguments to optim, such as lower and upper bounds

Details

Primary periods could represent spatial or temporal sampling replicates. For example, you could have several spatial sub-units within each site, where each sub-unit was then sampled repeatedly. This is a frequent design for eDNA studies. Or, you could have multiple primary periods of sampling at each site (conducted at different times within a season), each of which contains several secondary sampling periods. In both cases the robust design structure can be used to estimate an availability probability in addition to detection probability. See Kery and Royle (2015) 10.10 for more details.

Value

An object of class unmarkedFitGOccu

gpcount   *Generalized binomial N-mixture model for repeated count data*

Description

Fit the model of Chandler et al. (2011) to repeated count data collected using the robust design. This model allows for inference about population size, availability, and detection probability.

Usage

```
gpcount(lambdaformula, phiformula, pformula, data,
mixture = c("P", "NB", "ZIP"), K, starts, method = "BFGS", se = TRUE,
engine = c("C", "R"), threads=1, ...)
```

Arguments

lambdaformula	Right-hand sided formula describing covariates of abundance.
phiformula	Right-hand sided formula describing availability covariates
pformula	Right-hand sided formula for detection probability covariates
data	An object of class unmarkedFrameGPC
mixture	Either "P", "NB", or "ZIP" for Poisson, negative binomial, or zero-inflated Poisson distributions
K	The maximum possible value of M, the super-population size.
starts	Starting values
method	Optimization method used by optim
se	Logical. Should standard errors be calculated?
engine	Either "C" or "R" for the C++ or R versions of the likelihood. The C++ code is faster, but harder to debug.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

The latent transect-level super-population abundance distribution $f(M|\theta)$ can be set as either a Poisson, negative binomial, or zero-inflated Poisson random variable, depending on the setting of the mixture argument. The expected value of M_i is λ_i. If $M_i \sim NB$, then an additional parameter, α, describes dispersion (lower α implies higher variance). If $M_i \sim ZIP$, then an additional zero-inflation parameter ψ is estimated.

The number of individuals available for detection at time j is a modeled as binomial: $N_{ij} \sim Binomial(M_i, \phi_{ij})$.

The detection process is also modeled as binomial: $y_{ikj} \sim Binomial(N_{ij}, p_{ikj})$.

Parameters λ, ϕ and p can be modeled as linear functions of covariates using the log, logit and logit links respectively.

Value

An object of class unmarkedFitGPC

Note

In the case where availability for detection is due to random temporary emigration, population density at time j, D(i,j), can be estimated by N(i,j)/plotArea.

This model is also applicable to sampling designs in which the local population size is closed during the J repeated counts, and availability is related to factors such as the probability of vocalizing. In this case, density can be estimated by M(i)/plotArea.

If availability is a function of both temporary emigration and other processess such as song rate, then density cannot be directly estimated, but inference about the super-population size, M(i), is possible.

Three types of covariates can be supplied, site-level, site-by-year-level, and observation-level. These must be formatted correctly when organizing the data with unmarkedFrameGPC

```

IDS   *Fit the integrated distance sampling model of Kery et al. (2022).*

Description

Model abundance using a combination of distance sampling data (DS) and other similar data types, including simple point counts (PC) and occupancy/detection-nondetection (OC/DND) data.

Usage

```
IDS(lambdaformula = ~1, detformulaDS = ~1, detformulaPC = NULL, detformulaOC = NULL,
    dataDS, dataPC = NULL, dataOC = NULL, availformula = NULL,
    durationDS = NULL, durationPC = NULL, durationOC = NULL, keyfun = "halfnorm",
    maxDistPC, maxDistOC, K = 100, unitsOut = "ha",
    starts = NULL, method = "BFGS", ...)
```

Arguments

lambdaformula	Formula for abundance
detformulaDS	Formula for distance-based (DS) detection probability
detformulaPC	Formula for point count detection probability. If NULL, will share a model with DS detection probability
detformulaOC	Formula for occupancy/detection-nondetection detection probability. If NULL, will share a model with DS detection probability
dataDS	An object of class unmarkedFrameDS. Required
dataPC	An object of class unmarkedFramePCount. If NULL, no PC data will be used in the model

dataOC	An object of class unmarkedFrameOccu. If NULL, no OC/DND data will be used in the model
availformula	Optional. If specified, formula for availability. Only possible to use if you have variable detection survey lengths (see below)
durationDS	Optional. Vector of survey durations at each distance sampling site
durationPC	Optional. Vector of survey durations at each PC site
durationOC	Optional. Vector of survey durations at each OC/DND site
keyfun	Distance sampling key function; either "halfnorm" or "exp"
maxDistPC	Maximum observation distance for PC surveys; defaults to maximum of distance bins from the distance sampling data
maxDistOC	Maximum observation distance for OC/DND surveys; defaults to maximum of distance bins from the distance sampling data
K	Integer, upper bound for integrating out latent abundance. Only used if you have included OC/DND data
unitsOut	Units of density for output. Either "ha" or "kmsq" for hectares and square kilometers, respectively
starts	A numeric vector of starting values for the model parameters
method	Optimization method used by [optim](#)
...	Additional arguments to optim, such as lower and upper bounds

Details

This function facilitates a combined analysis of distance sampling data (DS) with other similar data types, including simple point counts (PC) and occupancy/detection-nondetection (OC/DND) data. The combined approach capitalizes on the strengths and minimizes the weaknesses of each type. The PC and OC/DND data are viewed as latent distance sampling surveys with an underlying abundance model shared by all data types. All analyses must include some distance sampling data, but can include either PC or DND data or both. If surveys are of variable duration, it is also possible to estimate availability.

Input data must be provided as a series of separate unmarkedFrames: unmarkedFrameDS for the distance sampling data, unmarkedFramePCount for the point count data, and unmarkedFrameOccu for OC/DND data. See the help files for these objects for guidance on how to organize the data.

Value

An object of class unmarkedFitIDS

Note

Simulations indicated estimates of availability were very unreliable when including detection/non-detection data, so the function will not allow you to use DND data and estimate availability at the same time. In general estimation of availability can be difficult; use simulations to see how well it works for your specific situation.

imputeMissing   *A function to impute missing entries in continuous obsCovs*

Description

This function uses an ad-hoc averaging approach to impute missing entries in obsCovs. The missing entry is replaced by an average of the average for the site and the average for the visit number.

Usage

```
imputeMissing(umf, whichCovs = seq(length=ncol(obsCovs(umf))))
```

Arguments

umf	The data set who's obsCovs are being imputed.
whichCovs	An integer vector giving the indices of the covariates to be imputed. This defaults to all covariates in obsCovs.

Value

A version of umf that has the requested obsCovs imputed.

Author(s)

Ian Fiske

Examples

```
data(frogs)
pcru.obscovs <- data.frame(MinAfterSunset=as.vector(t(pcru.data[,,1])),
     Wind=as.vector(t(pcru.data[,,2])),
     Sky=as.vector(t(pcru.data[,,3])),
     Temperature=as.vector(t(pcru.data[,,4])))
pcruUMF <- unmarkedFrameOccu(y = pcru.bin, obsCovs = pcru.obscovs)
pcruUMF.i1 <- imputeMissing(pcruUMF)
pcruUMF.i2 <- imputeMissing(pcruUMF, whichCovs = 2)
```

issj   *Distance-sampling data for the Island Scrub Jay (*Aphelocoma insularis*)*

Description

Data were collected at 307 survey locations ("point transects") on Santa Cruz Island, California during the Fall of 2008. The distance data are binned into 3 distance intervals [0-100], (100-200], and (200-300]. The coordinates of the survey locations as well as 3 habitat covariates are also included.

Usage

```
data(issj)
```

Format

A data frame with 307 observations on the following 8 variables.

`issj[0-100]` Number of individuals detected within 100m

`issj(100-200]` Detections in the interval (100-200m]

`issj(200-300]` Detections in the interval (200-300m]

`x` Easting (meters)

`y` Northing (meters)

`elevation` Elevation in meters

`forest` Forest cover

`chaparral` Chaparral cover

jay | *European Jay data from the Swiss Breeding Bird Survey 2002*

Description

The Swiss breeding bird survey ("Monitoring Haufige Brutvogel" MHB) has monitored the populations of 150 common species since 1999. The MHB sample consists of 267 1-km squares that are laid out as a grid across Switzerland. Fieldwork is conducted by about 200 skilled birdwatchers, most of them volunteers. Avian populations are monitored using a simplified territory mapping protocol, where each square is surveyed up to three times during the breeding season (only twice above the tree line). Surveys are conducted along a transect that does not change over the years.

The list jay has the data for European Jay territories for 238 sites surveyed in 2002.

Usage

```
data("jay")
```

Format

jay is a list with 3 elements:

caphist a data frame with rows for 238 sites and columns for each of the observable detection histories. For the sites visited 3 times, these are "100", "010", "001", "110", "101", "011", "111". Sites visited twice have "10x", "01x", "11x".

Each row gives the number of territories with the corresponding detection history, with NA for the detection histories not applicable: sites visited 3 times have NAs in the last 3 columns while those visited twice have NAs in the first 7 columns.

sitescovs a data frame with rows for 238 sites, and the following columns:

1. elev : the mean elevation of the quadrat, m.
2. length : the length of the route walked in the quadrat, km.
3. forest : percentage forest cover.

covinfo a data frame with rows for 238 sites, and the following columns:

1. x, y : the coordinates of the site.

2. date1, date2, date3 : the Julian date of the visit, with 1 April = 1. Sites visited twice have NA in the 3rd column.

3. dur1, dur2, dur3 : the duration of the survey, mins. For 10 visits the duration is not available, so there are additional NAs in these columns.

Note

In previous versions, jay had additional information not required for the analysis, and a data frame with essentially the same information as the Switzerland data set.

---

lambda2psi   *Convert Poisson mean (lambda) to probability of occurrence (psi).*

Description

Abundance and occurrence are fundamentally related.

Usage

```
lambda2psi(lambda)
```

Arguments

lambda   Numeric vector with values >= 0

Value

A vector of psi values of the same length as lambda.

See Also

[pcount](), [multinomPois](), [distsamp]()

Examples

```
lambda2psi(0:5)
```

linearComb-methods   *Methods for Function linearComb in Package 'unmarked'*

Description

Methods for function linearComb in Package 'unmarked'

Methods

obj = "unmarkedEstimate", coefficients = "matrixOrVector" Typically called internally

obj = "unmarkedFit", coefficients = "matrixOrVector" Returns linear combinations of parameters from a fitted model. Coefficients are supplied through coefficients. The required argument type specifies which model estimate to use. You can use names(fittedmodel) to view possible values for the type argument.

Examples

```
data(ovendata)
ovenFrame <- unmarkedFrameMPois(ovendata.list$data,
siteCovs=as.data.frame(scale(ovendata.list$covariates[,-1])), type = "removal")
fm <- multinomPois(~ 1 ~ ufc + trba, ovenFrame)
linearComb(fm, c(1, 0.5, 0.5), type = "state")
linearComb(fm, matrix(c(1, 0.5, 0.5, 1, 0, 0, 1, 0, 0.5), 3, 3,
  byrow=TRUE), type="state")
```

---

linetran	*Simulated line transect data*

Description

Response matrix of animals detected in four distance classes plus transect lengths and two covariates.

Usage

```
data(linetran)
```

Format

A data frame with 12 observations on the following 7 variables.

dc1 Counts in distance class 1 [0-5 m]

dc2 Counts in distance class 2 [5-10 m]

dc3 Counts in distance class 3 [10-15 m]

dc4 Counts in distance class 4 [15-20 m]

Length Transect lengths in km

area Numeric covariate

habitat a factor with levels A and B

Examples

```
data(linetran)
linetran

# Format for distsamp()
ltUMF <- with(linetran, {
        unmarkedFrameDS(y = cbind(dc1, dc2, dc3, dc4),
        siteCovs = data.frame(Length, area, habitat),
        dist.breaks = c(0, 5, 10, 15, 20),
        tlength = linetran$Length * 1000, survey = "line", unitsIn = "m")
        })
```

---

makePiFuns   *Create functions to compute multinomial cell probabilities*

Description

These are factory functions that generate piFuns with the required defaults, which are enclosed within the environment of the piFun. See the main entry for piFuns.

Usage

```
makeRemPiFun(times)
makeCrPiFun(nOcc)
makeCrPiFunMb(nOcc)
makeCrPiFunMh(nOcc)
```

Arguments

times   a vector of times for each interval, length(times) is the number of survey occasions; can be all 1's if times are the same.

nOcc   the number of survey occasions

Details

makeRemPiFun produces a piFun for a removal model with the required number of occasions and potentially varying time intervals. The input to the piFun must be probabilities *per unit time*. This is a generalisation of the piFun in the Examples section of piFuns.

makeCrPiFun produces a piFun for a standard capture-recapture model, M0, Mt or Mx. Probabilities of detection may vary across occasions. See Kery & Royle (2016) section 7.8.1.

makeCrPiFunMb produces a piFun for a capture-recapture model with a behavioral response after the first capture, Mb. Probabilities of detection are constant across occasions. The first column is the probability of detection for animals not caught before, column #2 is for animals after the first capture. The remaining columns are ignored. See Kery & Royle (2016) section 7.8.2.

makeCrPiFunMh produces a piFun for a capture-recapture model with individual heterogeneity in detection probability, Mh, using a logit-normal distribution. Probabilities of detection are constant across occasions. The first column is the mean of the logit-normal on the probability scale. Cell p[1, 2] is a value in [0, 1] which controls the spread of the distribution. The remaining cells are ignored. See Kery & Royle (2016) section 7.8.3.

Value

A piFun with the appropriate defaults.

masspcru   *Massachusetts North American Amphibian Monitoring Program Data*

Description

masspcru contains NAAMP data for Pseudacris crucifer (pcru) in Massachusetts from 2001 to 2007 in the raw long format.

Usage

```
data(masspcru)
```

Format

Data frame with

SurveyYear Year of data collection.

RouteNumStopNum Stop number.

JulianDate Day of year.

Pcru Observed calling index.

MinAfterSunset Minutes after sunset of the observation.

Temperature Temperature measured during observation.

Details

These data come from the North American Amphibian Monitoring Program. Please see the reference below for more details.

str(masspcru)
```

MesoCarnivores *Occupancy data for coyote, red fox, and bobcat*

Description

Occupancy data and site covariates for coyote, red fox, and bobcat from 1437 camera trap sites sampled 3 times. Each sampling period represents one week. This data is a simplified form of the dataset used by Rota et al. (2016).

Usage

```
data(MesoCarnivores)
```

Format

A list with four elements:

bobcat A 1437x3 occupancy matrix for bobcat

coyote A 1437x3 occupancy matrix for coyote

redfox A 1437x3 occupancy matrix for red fox

sitecovs A data frame containing covariates for the 1437 sites, with the following columns:

Dist_5km Proportion of disturbed land in 5 km radius

HDens_5km Housing density in 5 km radius

Latitude Latitude / 100

Longitude Longitude / 100

People_site Number of photos of people at site / 1000

Trail 1 if camera was on trail, 0 if not

modSel   *Model selection on a list of* unmarked *model fits*

Description

Model selection results from an unmarkedFitList

Arguments

object   an object of class "unmarkedFitList" created by the function [fitList](#).

nullmod   optional character naming which model in the fitList contains results from the
                null model. Only used in calculation of Nagelkerke's R-squared index.

Value

An object of class unmarkedModSel.

Note

Two requirements exist to conduct AIC-based model-selection and model-averaging in unmarked.
First, the data objects (ie, unmarkedFrames) must be identical among fitted models. Second, the
response matrix must be identical among fitted models after missing values have been removed.
This means that if a response value was removed in one model due to missingness, it needs to be
removed from all models.

multinomPois   *Multinomial-Poisson Mixtures Model*

Description

Fit the multinomial-Poisson mixture model to data collected using survey methods such as removal sampling or double observer sampling.

Usage

```
multinomPois(formula, data, starts, method = "BFGS",
    se = TRUE, engine=c("C","R","TMB"), ...)
```

Arguments

formula	double right-hand side formula for detection and abundance covariates, in that order.
data	unmarkedFrame supplying data.
starts	vector of starting values.
method	Optimization method used by [optim]().
se	logical specifying whether or not to compute standard errors.
engine	Either "C" to use fast C++ code or "R" to use native R code during the optimization.
...	Additional arguments to optim, such as lower and upper bounds

Details

This function takes advantage of the closed form of the integrated likelihood when a latent Poisson distribution is assumed for abundance at each site and a multinomial distribution is taken for the observation state. Many common sampling methods can be framed in this context. For example, double-observer point counts and removal sampling can be analyzed with this function by specifying the proper multinomial cell probablilities. This is done with by supplying the appropriate function (piFun) argument. removalPiFun and doublePiFun are supplied as example cell probability functions.

Value

unmarkedFit object describing the model fit.

multmixOpen   *Open population multinomial N-mixture model*

Description

Fit the model of Dail and Madsen (2011) and Hostetler and Chandler (2015) for designs involving repeated counts that yield multinomial outcomes. Possible data collection methods include repeated removal sampling and double observer sampling.

Usage

```
multmixOpen(lambdaformula, gammaformula, omegaformula, pformula,
    data, mixture=c("P", "NB", "ZIP"), K,
    dynamics=c("constant", "autoreg", "notrend", "trend", "ricker", "gompertz"),
    fix=c("none", "gamma", "omega"), immigration=FALSE, iotaformula = ~1,
    starts, method="BFGS", se=TRUE, ...)
```

Arguments

lambdaformula	Right-hand sided formula for initial abundance
gammaformula	Right-hand sided formula for recruitment rate (when dynamics is "constant", "autoreg", or "notrend") or population growth rate (when dynamics is "trend", "ricker", or "gompertz")
omegaformula	Right-hand sided formula for apparent survival probability (when dynamics is "constant", "autoreg", or "notrend") or equilibrium abundance (when dynamics is "ricker" or "gompertz")
pformula	A right-hand side formula describing the detection function covariates
data	An object of class unmarkedFrameMMO
mixture	String specifying mixture: "P", "NB", or "ZIP" for the Poisson, negative binomial, or zero-inflated Poisson distributions respectively
K	Integer defining upper bound of discrete integration. This should be higher than the maximum observed count and high enough that it does not affect the parameter estimates. However, the higher the value the slower the computation
dynamics	Character string describing the type of population dynamics. "constant" indicates that there is no relationship between omega and gamma. "autoreg" is an auto-regressive model in which recruitment is modeled as gamma*N[i,t-1]. "notrend" model gamma as lambda*(1-omega) such that there is no temporal trend. "trend" is a model for exponential growth, N[i,t] = N[i,t-1]*gamma, where gamma in this case is finite rate of increase (normally referred to as lambda). "ricker" and "gompertz" are models for density-dependent population growth. "ricker" is the Ricker-logistic model, N[i,t] = N[i,t-1]*exp(gamma*(1-N[i,t-1]/omega)), where gamma is the maximum instantaneous population growth rate (normally referred to as r) and omega is the equilibrium abundance (normally referred to as K). "gompertz" is a modified version of the Gompertz-logistic model, N[i,t] = N[i,t-1]*exp(gamma*(1-log(N[i,t-1]+1)/log(omega+1))), where the interpretations of gamma and omega are similar to in the Ricker model
fix	If "omega", omega is fixed at 1. If "gamma", gamma is fixed at 0
immigration	Logical specifying whether or not to include an immigration term (iota) in population dynamics
iotaformula	Right-hand sided formula for average number of immigrants to a site per time step
starts	Vector of starting values
method	Optimization method used by optim
se	Logical specifying whether or not to compute standard errors
...	Additional arguments to optim, such as lower and upper bounds

Details

These models generalize multinomial N-mixture models (Royle et al. 2004) by relaxing the closure assumption (Dail and Madsen 2011, Hostetler and Chandler 2015, Sollmann et al. 2015).

The models include two or three additional parameters: gamma, either the recruitment rate (births and immigrations), the finite rate of increase, or the maximum instantaneous rate of increase;

omega, either the apparent survival rate (deaths and emigrations) or the equilibrium abundance (carrying capacity); and iota, the number of immigrants per site and year. Estimates of population size at each time period can be derived from these parameters, and thus so can trend estimates. Or, trend can be estimated directly using dynamics="trend".

When immigration is set to FALSE (the default), iota is not modeled. When immigration is set to TRUE and dynamics is set to "autoreg", the model will separately estimate birth rate (gamma) and number of immigrants (iota). When immigration is set to TRUE and dynamics is set to "trend", "ricker", or "gompertz", the model will separately estimate local contributions to population growth (gamma and omega) and number of immigrants (iota).

The latent abundance distribution, $f(N|\theta)$ can be set as a Poisson, negative binomial, or zero-inflated Poisson random variable, depending on the setting of the mixture argument, mixture = "P", mixture = "NB", mixture = "ZIP" respectively. For the first two distributions, the mean of N_i is λ_i. If $N_i \sim NB$, then an additional parameter, α, describes dispersion (lower α implies higher variance). For the ZIP distribution, the mean is $\lambda_i(1 - \psi)$, where psi is the zero-inflation parameter.

For "constant", "autoreg", or "notrend" dynamics, the latent abundance state following the initial sampling period arises from a Markovian process in which survivors are modeled as $S_{it} \sim Binomial(N_{it-1}, \omega_{it})$, and recruits follow $G_{it} \sim Poisson(\gamma_{it})$. Alternative population dynamics can be specified using the dynamics and immigration arguments.

λ_i, γ_{it}, and ι_{it} are modeled using the the log link. p_{ijt} is modeled using the logit link. ω_{it} is either modeled using the logit link (for "constant", "autoreg", or "notrend" dynamics) or the log link (for "ricker" or "gompertz" dynamics). For "trend" dynamics, ω_{it} is not modeled.

The detection process is modeled as multinomial: $\mathbf{y_{it}} \sim Multinomial(N_{it}, \pi_{it})$, where π_{ijt} is the multinomial cell probability for plot i at time t on occasion j.

Options for the detection process include equal-interval removal sampling ("removal"), double observer sampling ("double"), or dependent double-observer sampling ("depDouble"). This option is specified when setting up the data using unmarkedFrameMMO. Note that unlike the related functions multinomPois and gmultmix, custom functions for the detection process (i.e., piFuns) are not supported. To request additional options contact the author.

Value

An object of class unmarkedFitMMO

Warning

This function can be extremely slow, especially if there are covariates of gamma or omega. Consider testing the timing on a small subset of the data, perhaps with se=FALSE. Finding the lowest value of K that does not affect estimates will also help with speed.

Note

When gamma or omega are modeled using year-specific covariates, the covariate data for the final year will be ignored; however, they must be supplied.

If the time gap between primary periods is not constant, an M by T matrix of integers should be supplied to unmarkedFrameMMO using the primaryPeriod argument.

Secondary sampling periods are optional, but can greatly improve the precision of the estimates.

nmixTTD   *Fit the N-mixture Time-to-detection Model of Strebel et al. (2021)*

Description

Fit N-mixture models with time-to-detection data.

Usage

```
nmixTTD(stateformula= ~1, detformula = ~1, data, K=100,
    mixture = c("P","NB"), ttdDist = c("exp", "weibull"), starts, method="BFGS",
    se=TRUE, engine = c("C", "R"), threads = 1, ...)
```

Arguments

stateformula	Right-hand sided formula for the abundance at each site.
detformula	Right-hand sided formula for mean time-to-detection.
data	unmarkedFrameOccuTTD object that supplies the data (see unmarkedFrameOccuTTD). Note that only single-season models are supported by nmixTTD.
K	The upper summation index used to numerically integrate out the latent abundance. This should be set high enough so that it does not affect the parameter estimates. Computation time will increase with K.

mixture	String specifying mixture distribution: "P" for Poisson or "NB" for negative binomial.
ttdDist	Distribution to use for time-to-detection; either "exp" for the exponential, or "weibull" for the Weibull, which adds an additional shape parameter k.
starts	optionally, initial values for parameters in the optimization.
method	Optimization method used by optim.
se	logical specifying whether or not to compute standard errors.
engine	Either "C" or "R" to use fast C++ code or native R code during the optimization.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

This model extends time-to-detection (TTD) occupancy models to estimate site abundance using data from single or repeated visits. Latent abundance can be modeled as Poisson (mixture="P") or negative binomial (mixture="NB"). Time-to-detection can be modeled as an exponential (ttdDist="exp") or Weibull (ttdDist="weibull") random variable with rate parameter λ and, for the Weibull, an additional shape parameter k. Note that occuTTD puts covariates on λ and not $1/\lambda$, i.e., the expected time between events.

Assuming that there are N independent individuals at a site, and all individuals have the same individual detection rate, the expected detection rate across all individuals λ is equal to the the individual-level detection rate r multiplied by the number of individuals present N.

In the case where there are no detections before the maximum sample time at a site (surveyLength) is reached, we are not sure if the site has $N = 0$ or if we just didn't wait long enough for a detection. We therefore must censor (C the exponential or Weibull distribution at the maximum survey length, $Tmax$. Thus, assuming true abundance at site i is N_i, and an exponential distribution for the TTD y_i (parameterized with the rate), then:

$$y_i \sim Exponential(r_i * N_i)C(Tmax)$$

Note that when $N_i = 0$, the exponential rate $lambda = 0$ and the scale is therefore $1/0 = Inf$, and thus the value will be censored at $Tmax$.

Because in unmarked values of NA are typically used to indicate missing values that were a result of the sampling structure (e.g., lost data), we indicate a censored y_i in nmixTTD instead by setting $y_i = Tmax_i$ in the y matrix provided to unmarkedFrameOccuTTD. You can provide either a single value of $Tmax$ to the surveyLength argument of unmarkedFrameOccuTTD, or provide a matrix, potentially with a unique value of $Tmax$ for each value of y. Note that in the latter case the value of y that will be interpreted by nmixTTD as a censored observation (i.e., $Tmax$) will differ between observations!

Value

unmarkedFitNmixTTD object describing model fit.

nonparboot   *Get non-parametric bootstrap samples from an* unmarked *model*

Description

Resamples sites (with replacement) from an unmarkedFit object and re-fits the model, to generate new non-parametric bootstrap samples of estimates. These samples can then be used by vcov in order to get bootstrap-based estimates of standard errors.

Usage

```
## S4 method for signature 'unmarkedFit'
nonparboot(object, B = 1, keepOldSamples = TRUE, ...)
```

Arguments

object	A unmarkedFit object
B	The number of bootstrap samples to get
keepOldSamples	Should previously generated bootstrap samples be retained?
...	Other arguments, currently ignored

Details

Calling nonparboot on an unmarkedFit returns the original unmarkedFit, with the bootstrap samples added on. Then subsequent calls to vcov with the argument method="nonparboot" will use these bootstrap samples. Additionally, standard errors of derived estimates from either linearComb or backTransform can be instructed to use bootstrap samples by providing the argument method = "nonparboot".

For all fitting functions, only sites are re-sampled. In previous versions of unmarked both sites and occasions of occu and occuRN fits were re-sampled, but now only sites are re-sampled for these fit types to match the other fit types.

Note: by default, if the model fit to a new resampled dataset results in an error or a convergence failure, nonparboot will continually re-sample and re-fit until this is no longer the case. This could result in the function hanging.

Examples

```
data(ovendata)
ovenFrame <- unmarkedFrameMPois(ovendata.list$data,
siteCovs=as.data.frame(scale(ovendata.list$covariates[,-1])), type = "removal")
(fm <- multinomPois(~ 1 ~ ufc + trba, ovenFrame))
fm <- nonparboot(fm, B = 20) # should use larger B in real life.
vcov(fm, method = "hessian")
vcov(fm, method = "nonparboot")
avg.abundance <- backTransform(linearComb(fm, type = "state", coefficients = c(1, 0, 0)))
```

```
## Bootstrap sample information propagates through to derived quantities.
vcov(avg.abundance, method = "hessian")
vcov(avg.abundance, method = "nonparboot")
SE(avg.abundance, method = "nonparboot")
```

| occu | *Fit the MacKenzie et al. (2002) Occupancy Model* |

Description

This function fits the single season occupancy model of MacKenzie et al (2002).

Usage

```
occu(formula, data, knownOcc=numeric(0), linkPsi=c("logit", "cloglog"),
             starts, method="BFGS", se=TRUE, engine=c("C", "R", "TMB"),
             threads = 1, ...)
```

Arguments

formula	Double right-hand side formula describing covariates of detection and occupancy in that order.
data	An [unmarkedFrameOccu](#) object
knownOcc	Vector of sites that are known to be occupied. These should be supplied as row numbers of the y matrix, eg, c(3,8) if sites 3 and 8 were known to be occupied a priori.
linkPsi	Link function for the occupancy model. Options are "logit" for the standard occupancy model or "cloglog" for the complimentary log-log link, which relates occupancy to site-level abundance. See details.
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
se	Logical specifying whether or not to compute standard errors.
engine	Code to use for optimization. Either "C" for fast C++ code, "R" for native R code, or "TMB" for Template Model Builder. "TMB" is used automatically if your formula contains random effects.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

See [unmarkedFrame](#) and [unmarkedFrameOccu](#) for a description of how to supply data to the data argument.

occu fits the standard occupancy model based on zero-inflated binomial models (MacKenzie et al. 2006, Royle and Dorazio 2008). The occupancy state process (z_i) of site i is modeled as

$$z_i \sim Bernoulli(\psi_i)$$

The observation process is modeled as

$$y_{ij}|z_i \sim Bernoulli(z_i p_{ij})$$

By default, covariates of ψ_i and p_{ij} are modeled using the logit link according to the formula argument. The formula is a double right-hand sided formula like ~ detform ~ occform where detform is a formula for the detection process and occform is a formula for the partially observed occupancy state. See [formula](#) for details on constructing model formulae in R.

When linkPsi = "cloglog", the complimentary log-log link function is used for psi instead of the logit link. The cloglog link relates occupancy probability to the intensity parameter of an underlying Poisson process (Kery and Royle 2016). Thus, if abundance at a site is can be modeled as N_i $Poisson(\lambda_i)$, where $log(\lambda_i) = \alpha + \beta * x$, then presence/absence data at the site can be modeled as Z_i $Binomial(\psi_i)$ where $cloglog(\psi_i) = \alpha + \beta * x$.

Value

unmarkedFitOccu object describing the model fit.

occuComm   *Fit a community occupancy model with species-level random effects*

Description

This function fits a multi-species, community occupancy model with random intercepts and slopes by species.

Usage

```
occuComm(formula, data, starts, method="BFGS", se=TRUE, ...)
```

Arguments

formula	Double right-hand side formula describing covariates of detection and occupancy in that order. It is also possible to include random intercepts using lme4-type syntax.
data	An [unmarkedFrameOccuComm](#) object
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
se	Logical specifying whether or not to compute standard errors.
...	Additional arguments to optim, such as lower and upper bounds

Details

In a community occupancy model, detection-nondetection data from multiple species are analyzed together. Intercepts and slopes in the model are species-specific and come from common distributions, allowing for information sharing across species. This structure also allows estimation of site richness. For example, suppose you have sites indexed i, occasions j and species s. The true occupancy state at a site is

$$z_{is} \sim \text{Bernoulli}(\psi_{is})$$

with detection data y_{ijs} modeled as

$$y_{ijs} \sim \text{Bernoulli}(p_{ijs} \cdot z_{is})$$

Occupancy probability ψ_{is} can be modeled as a function of covariates with species-specific random intercepts and slopes coming from common distributions:

$$\psi_{is} = \text{logit}(\beta_{0,s} + \beta_{i,s} \cdot x_i)$$

$$\beta_{0,s} \sim \text{Normal}(\mu_{\beta_0}, \sigma_{\beta_0})$$

$$\beta_{1,s} \sim \text{Normal}(\mu_{\beta_1}, \sigma_{\beta_1})$$

A similar structure can be implemented for detection probability p.

Note there is a variety of this model that incorporates hypothetical completely unobserved species using data augmentation, but that is not a model that `unmarked` is able to fit at this time.

See the vignette for `occuComm` and Kery and Royle (2016), Section 11.6 for more details.

Value

unmarkedFitOccuComm object describing the model fit.

occuCOP   *Fit the occupancy model using count data*

Description

This function fits a single season occupancy model using count data.

Usage

```
occuCOP(data,
        psiformula = ~1, lambdaformula = ~1,
        psistarts, lambdastarts, starts,
        method = "BFGS", se = TRUE,
        engine = c("C", "R"), na.rm = TRUE,
        return.negloglik = NULL, L1 = FALSE, ...)
```

Arguments

data	An [unmarkedFrameOccuCOP](#) object created with the [unmarkedFrameOccuCOP](#) function.
psiformula	Formula describing the occupancy covariates.
lambdaformula	Formula describing the detection covariates.
psistarts	Vector of starting values for likelihood maximisation with [optim](#) for occupancy probability ψ. These values must be logit-transformed (with [qlogis](#)) (see details). By default, optimisation will start at 0, corresponding to an occupancy probability of 0.5 (plogis(0) is 0.5).
lambdastarts	Vector of starting values for likelihood maximisation with [optim](#) for detection rate λ. These values must be log-transformed (with [log](#)) (see details). By default, optimisation will start at 0, corresponding to detection rate of 1 (exp(0) is 1).
starts	Vector of starting values for likelihood maximisation with [optim](#). If psistarts and lambdastarts are provided, starts = c(psistarts, lambdastarts).
method	Optimisation method used by [optim](#).
se	Logical specifying whether to compute (se=TRUE) standard errors or not (se=FALSE).

engine	Code to use for optimisation. Either `"C"` for fast C++ code, or `"R"` for native R code.
na.rm	Logical specifying whether to fit the model (`na.rm=TRUE`) or not (`na.rm=FALSE`) if there are NAs in the [unmarkedFrameOccuCOP](#) object.
return.negloglik	
	A list of vectors of parameters (`c(psiparams, lambdaparams)`). If specified, the function will not maximise likelihood but return the negative log-likelihood for the those parameters in the `nll` column of a dataframe. See an example below.
L1	Logical specifying whether the length of observations (`L`) are purposefully set to 1 (`L1=TRUE`) or not (`L1=FALSE`).
...	Additional arguments to pass to [optim](#), such as lower and upper bounds or a list of control parameters.

Details

See [unmarkedFrameOccuCOP](#) for a description of how to supply data to the `data` argument. See [unmarkedFrame](#) for a more general documentation of unmarkedFrame objects for the different models implemented in **unmarked**.

The COP occupancy model:

occuCOP fits a single season occupancy model using count data, as described in Pautrel et al. (2023).

The **occupancy sub-model** is:

$$z_i \sim \text{Bernoulli}(\psi_i)$$

- With z_i the occupany state of site i. $z_i = 1$ if site i is occupied by the species, *i.e.* if the species is present in site i. $z_i = 0$ if site i is not occupied.
- With ψ_i the occupancy probability of site i.

The **observation sub-model** is:

$$N_{ij}|z_i = 1 \sim \text{Poisson}(\lambda_{ij}L_{ij}) \qquad N_{ij}|z_i = 0 \sim 0$$

- With N_{ij} the count of detection events in site i during observation j.
- With λ_{ij} the detection rate in site i during observation j (*for example, 1 detection per day.*).
- With L_{ij} the length of observation j in site i (*for example, 7 days.*).

What we call "observation" (j) here can be a sampling occasion, a transect, a discretised session. Consequently, the unit of λ_{ij} and L_{ij} can be either a time-unit (day, hour, ...) or a space-unit (kilometer, meter, ...).

The transformation of parameters ψ and λ: In order to perform unconstrained optimisation, parameters are transformed.

The occupancy probability (ψ) is transformed with the logit function (`psi_transformed = qlogis(psi)`). It can be back-transformed with the "inverse logit" function (`psi = plogis(psi_transformed)`).

The detection rate (λ) is transformed with the log function (`lambda_transformed = log(lambda)`). It can be back-transformed with the exponential function (`lambda = exp(lambda_transformed)`).

Value

`unmarkedFitOccuCOP` object describing the model fit. See the [unmarkedFit](#) classes.

  "Forest" = mean(rowSums(y[landuse == "Forest", ]) > 0),
  "Grassland" = mean(rowSums(y[landuse == "Grassland", ]) > 0)
))
occuCOP(
  data = umf,
  psiformula = ~ landuse,
  lambdaformula = ~ wind,
  psistarts = qlogis(psi_init_covs))

# We can fit our model with a different optimisation algorithm.
occuCOP(data = umf, method = "Nelder-Mead")

# We can run our model with a C++ or with a R likelihood function.
## They give the same result.
occuCOP(data = umf, engine = "C", psistarts = 0, lambdastarts = 0)
occuCOP(data = umf, engine = "R", psistarts = 0, lambdastarts = 0)

## The C++ (the default) is faster.
system.time(occuCOP(data = umf, engine = "C", psistarts = 0, lambdastarts = 0))
system.time(occuCOP(data = umf, engine = "R", psistarts = 0, lambdastarts = 0))

## However, if you want to understand how the likelihood is calculated,
## you can easily access the R likelihood function.
print(occuCOP(data = umf, engine = "R", psistarts = 0, lambdastarts = 0)@nllFun)

# Finally, if you do not want to fit your model but only get the likelihood,
# you can get the negative log-likelihood for a given set of parameters.
occuCOP(data = umf, return.negloglik = list(
  c("psi" = qlogis(0.25), "lambda" = log(2)),
  c("psi" = qlogis(0.5), "lambda" = log(1)),
  c("psi" = qlogis(0.75), "lambda" = log(0.5))
))
```

occuFP	*Fit occupancy models when false positive detections occur (e.g., Royle and Link [2006] and Miller et al. [2011])*

Description

This function fits the single season occupancy model while allowing for false positive detections.

Usage

```
occuFP(detformula = ~ 1, FPformula = ~ 1, Bformula = ~ 1,
stateformula = ~ 1, data, starts, method="BFGS", se = TRUE, engine = "R", ...)
```

Arguments

detformula	formula describing covariates of detection.
FPformula	formula describing covariates of false positive detection probability.
Bformula	formula describing covariates of probability detections are certain.
stateformula	formula describing covariates of occupancy.
data	An [unmarkedFrameOccuFP](#) object
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
se	Logical specifying whether or not to compute standard errors.
engine	Currently only choice is R.
...	Additional arguments to optim, such as lower and upper bounds

Details

See [unmarkedFrame](#) and [unmarkedFrameOccuFP](#) for a description of how to supply data to the data argument.

occuFP fits an extension of the standard single-season occupancy model (MacKenzie et al. 2002), which allows false positive detections. The occupancy status of a site is the same way as with the [occu](#) function, where stateformula is used to specify factors that lead to differences in occupancy probabilities among sites.

The observation process differs in that both false negative and false positive errors are modeled for observations. The function allows data to be of 3 types. These types are specified using in unmarkedFrameOccuFP as type. Occassions are specified to belong to 1 of the 3 data types and all or a subset of the data types can be combined in the same model.

For type 1 data, the detection process is assumed to fit the assumptions of the standard MacKenzie model where false negative probabilities are estimated but false positive detections are assumed not to occur. If all of your data is of this type you should use occu to analyze data. The detection parameter p, which is modeled using the detformula is the only observation parameter for these data.

For type 2 data, both false negative and false positive detection probabilities are estimated. If all data is of this type the likelihood follows Royle and Link (2006). Both p (the true positive detection

probability) and fp (the false positive detection probability described by fpformula) are estimated for occassions when this data type occurs

For type 3 data, observations are assumed to include both certain detections (false positives assumed not to occur) and uncertain detections that may include false positive detections. When only this data type occurs, the estimator is the same as the multiple detection state model described in Miller et al. (2011). Three observation parameters occur for this data type: p - true positive detection probability, fp - false positive detection probability, and b - the probability a true positive detection was designated as certain.

When both type 1 and type 2 data occur, the estimator is equivalent to the multiple detection method model described in Miller et al. (2011). The frog data example in the same paper uses an analysis where type 1 (dipnet surveys) and type 3 (call surveys) data were used.

Data in the y matrix of the unmarked frame should be all 0s and 1s for type 1 and type 2 data. For type 3 data, uncertain detections are given a value of 1 and certain detections a value of 2.

Value

unmarkedFitOccuFP object describing the model fit.

occuMS   *Fit Multi-State Occupancy Models (Nichols et al. 2007, MacKenzie et
                          al. 2009)*

Description

This function fits single-season and dynamic multi-state occupancy models with both the multino-
mial and conditional binomial parameterizations.

Usage

```
occuMS(detformulas, psiformulas, phiformulas=NULL, data,
    parameterization=c("multinomial","condbinom"),
    starts, method="BFGS", se=TRUE, engine=c("C","R"), silent=FALSE, ...)
```

Arguments

detformulas	Character vector of formulas for detection probabilities. See details for a de-scription of how to order these formulas.
psiformulas	Character vector of formulas for occupancy probabilities. See details for a de-scription of how to order these formulas.
phiformulas	Character vector of formulas for state transition probabilities. Only used if you are fitting a dynamic model. See details for a description of how to order these formulas.
data	An [unmarkedFrameOccuMS](#) object
parameterization	
	Either "multinomial" for the multinomial parameterization (MacKenzie et al. 2009) which allows an arbitrary number of occupancy states, or "condbinom" for the conditional binomial parameterization (Nichols et al. 2007) which re-quires exactly 3 occupancy states. See details.
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).

se	Logical specifying whether or not to compute standard errors.
engine	Either "C" to use fast C++ code or "R" to use native R code during the optimization.
silent	Boolean; if TRUE, suppress warnings.
...	Additional arguments to optim, such as lower and upper bounds

Details

Traditional occupancy models fit data with exactly two states: detection and non-detection (MacKenzie et al. 2002). The occuMS function fits models to occupancy data for which there are greater than 2 states (Nichols et al 2007, MacKenzie et al. 2009). For example, detections may be further divided into multiple biologically relevant categories, e.g. breeding vs. non-breeding, or some/many individuals present. As with detection status, classification of these additional occupancy states is likely to be imperfect.

Multiple parameterizations for multi-state occupancy models have been proposed. The occuMS function fits two at present: the "conditional binomial" parameterization of Nichols et al. (2007), and the more general "multinomial" parameterization of MacKenzie et al. (2009). Both single-season and dynamic models are possible with occuMS (MacKenzie et al. 2009).

The conditional binomial parameterization (parameterization = 'condbinom') models occupancy and the presence or absence of an additional biological state of interest given the species is present (typically breeding status). Thus, there should be exactly 3 occupancy states in the data: 0 (non-detection); 1 (detection, no evidence of breeding); or 2 (detection, evidence of breeding).

Two state parameters are estimated: ψ, the probability of occupancy, and R, the probability of successful reproduction given an occupied state (although this could be some other binary biological condition). Covariates (in siteCovs) can be supplied for either or both of these parameters with the stateformulas argument, which takes a character vector of R-style formulas with length = 2, with formulas in the order (ψ, R). For example, to fit a model where ψ varies with a landcover covariate and R is constant, stateformulas = c('~landcover','~1').

There are three detection parameters associated with the conditional binomial parameterization: p_1, the probability of detecting the species given true state 1; p_2, the probability of detecting the species given true state 2; and δ, the probability of detecting state 2 (i.e., breeding), given that the species has been detected. See MacKenzie et al. (2009), pages 825-826 for more details. As with occupancy, covariates (in obsCovs) can be supplied for these detection probabilities with the detformulas argument, which takes a character vector of formulas with length = 3 in the order (p_1, p_2, δ). So, to fit a model where p_1 varies with temperature and the other two parameters are constant, detformulas = c('~temp','~1','~1').

The multinomial parameterization (parameterization = "multinomial") is more general, allowing an arbitrary number of occupancy states S. S - 1 occupancy probabilities ψ are estimated. Thus, if there are $S = 4$ occupancy states (0, 1, 2, 3), occuMS estimates ψ_1, ψ_2, and ψ_3 (the probability of state 0 can be obtained by subtracting the others from 1). Covariates can be supplied for each occupancy probability with a character vector with length $S - 1$, e.g. stateformulas = c('~landcover','~1','~1') where ψ_1 varies with landcover and ψ_2 and ψ_3 are constant.

The number of detection probabilities estimated quickly expands as S increases, equal to $S \times (S - 1)/2$. In the simplest case (when $S = 3$), there are 3 detection probabilities: p_{11}, the probability of detecting state 1 given true state 1; p_{12}, the probability of detecting state 1 given true state 2; and p_{22}, the probability of detecting state 2 given true state 2. Covariates can be supplied for

any or all of these detection probabilities with the `detformulas` argument, which takes a character vector of formulas with length = 3 in the order (p_{11}, p_{12}, p_{22}). So, to fit a model where p_{11} varies with temperature and the other two detection probabilities are constant, `detformulas` = `c('~temp','~1','~1')`. If there were $S = 4$ occupancy states, there are 6 estimated detection probabilities and the order is (p_{11}, p_{12}, p_{13}, p_{22}, p_{23}, p_{33}), and so on. See MacKenzie et al. (2009) for a more detailed explanation.

Dynamic (multi-season) models can be fit as well for both parameterizations (MacKenzie et al. 2009). In a standard dynamic occupancy model, additional parameters for probabilities of colonization (i.e., state 0 -> 1) and extinction (1 -> 0) are estimated. In a multi-state context, we must estimate a transition probability matrix (ϕ) between all possible states. You can provide formulas for some of the probabilities in this matrix using the `phiformulas` argument. The approach differs depending on parameterization.

For the conditional binomial parameterization, `phiformulas` is a character vector of length 6. The first three elements are formulas for the probability a site is occupied at time t given that it was previously in states 0, 1, or 2 at time $t-1$ (`phi0`, `phi1`, `phi2`). Elements 4-6 are formulas for the probability of reproduction (or other biological state) given state 0, 1, or 2 at time $t-1$ (`R0`, `R1`, `R2`). See `umf@phiOrder$cond_binom` for a reminder of the correct order, where `umf` is your `unmarkedFrameOccuMS`.

For the multinomial parameterization, `phiformulas` can be used to provide formulas for some transitions between different occupancy states. You can't give formulas for the probabilities of remaining in the same state between seasons to keep the model identifiable. Thus, if there are 3 possible states (0, 1, 2), `phiformulas` should contain 6 formulas for the following transitions: `p(0->1)`, `p(0->2)`, `p(1->0)`, `p(1->2)`, `p(2->0)`, `p(2->1)`, in that order (and similar for more than 3 states). The remaining probabilities of staying in the same state between seasons can be obtained via subtraction. See `umf@phiOrder$multinomial` for the correct order matching the number of states in your dataset.

See [unmarkedFrame](#) and [unmarkedFrameOccuMS](#) for a description of how to supply data to the `data` argument.

Value

unmarkedFitOccuMS object describing the model fit.

occuMulti   *Fit the multi-species occupancy model of Rota et al. (2016)*

Description

This function fits the multispecies occupancy model of Rota et al (2016).

Usage

```
occuMulti(detformulas, stateformulas, data, maxOrder, penalty=0, boot=30,
        starts, method="BFGS", se=TRUE, engine=c("C","R"), silent=FALSE, ...)
```

Arguments

detformulas	Character vector of formulas for the detection models, one per species.
stateformulas	Character vector of formulas for the natural parameters. To fix a natural parameter at 0, specify the corresponding formula as `"0"` or `"~0"`.
data	An [unmarkedFrameOccuMulti](#) object
maxOrder	Optional; specify maximum interaction order. Defaults to number of species (all possible interactions). Reducing this value may speed up optimization if you aren't interested in higher-order interactions.
penalty	Penalty term for likelihood. The total penalty is calculated as `penalty * 0.5 * sum(paramvals^2)`. Defaults to 0 (no penalty).
boot	Number of bootstrap samples to use to generate the variance-covariance matrix when `penalty > 0`.
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
se	Logical specifying whether or not to compute standard errors.
engine	Either "C" to use fast C++ code or "R" to use native R code during the optimization.
silent	Boolean; if `TRUE`, suppress warnings.
...	Additional arguments to optim, such as lower and upper bounds

Details

See [unmarkedFrame](#) and [unmarkedFrameOccuMulti](#) for a description of how to supply data to the data argument.

`occuMulti` fits the multispecies occupancy model from Rota et al. (2016), for two or more interacting species. The model generalizes the standard single-species occupancy model from MacKenzie et al. (2002). The latent occupancy state at site i for a set of s potentially interacting species is a vector $\mathbf{Z}_i$ of length s containing a sequence of the values 0 or 1. For example, when $s = 2$, the possible states are $[11]$, $[10]$, $[01]$, or $[00]$, corresponding to both species present, only species 1 or species 2 present, or both species absent, respectively. The latent state modeled as a multivariate Bernoulli random variable:

$$\mathbf{Z}_i \sim \mathrm{MVB}(\boldsymbol{\psi}_i)$$

where $\boldsymbol{\psi}_i$ is a vector of length 2^s containing the probability of each possible combination of 0s and 1s, such that $\sum \boldsymbol{\psi}_i = 1$.

For $s = 2$, the corresponding natural parameters f are

$$f_1 = \log\left(\frac{\psi_{10}}{\psi_{00}}\right)$$

$$f_2 = \log\left(\frac{\psi_{01}}{\psi_{00}}\right)$$

$$f_{12} = \log\left(\frac{\psi_{11}\psi_{00}}{\psi_{10}\psi_{01}}\right)$$

The natural parameters can then be modeled as linear functions of covariates. Covariates for each f must be specified with the stateformulas argument, which takes a character vector of individual formulas of length equal to the number of natural parameters (which in turn depends on the number of species in the model).

The observation process is similar to the standard single-species occupancy model, except that the observations $\mathbf{y}_{ij}$ at site i on occasion j are vectors of length s and there are independent values of detection probability p for each species s:

$$\mathbf{y}_{ij}|\mathbf{Z}_i \sim \text{MVB}(\mathbf{Z}_i p_{sij})$$

Independent detection models (potentially containing different covariates) must be provided for each species with the detformulas argument, which takes a character vector of individual formulas with length equal to the number of species s.

If you are having problems with separation or boundary estimates (indicated by very large parameter estimates and SEs), use of penalized likelihood may help: see Clipp et al. (2021). occuMulti supports use of the Bayes-inspired penalty of Hutchinson et al. (2015). You can set the penalty value manually using the penalty argument, or identify the optimal penalty using K-fold cross validation with the optimizePenalty function. See example below.

Value

unmarkedFitOccuMulti object describing the model fit.

occuPEN   *Fit the MacKenzie et al. (2002) Occupancy Model with the penalized*
                                 likelihood methods of Hutchinson et al. (2015)

Description

This function fits the occupancy model of MacKenzie et al (2002) with the penalized methods of Hutchinson et al (2015).

Usage

```
occuPEN(formula, data, knownOcc=numeric(0), starts, method="BFGS",
    engine=c("C", "R"), lambda=0, pen.type = c("Bayes","Ridge","MPLE"), ...)
```

Arguments

formula	Double right-hand side formula describing covariates of detection and occupancy in that order.
data	An [unmarkedFrameOccu](#) object
knownOcc	Vector of sites that are known to be occupied. These should be supplied as row numbers of the y matrix, eg, c(3,8) if sites 3 and 8 were known to be occupied a priori.
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
engine	Either "C" or "R" to use fast C++ code or native R code during the optimization.
lambda	Penalty weight parameter.
pen.type	Which form of penalty to use.
...	Additional arguments to optim, such as lower and upper bounds

Details

See [unmarkedFrame](#) and [unmarkedFrameOccu](#) for a description of how to supply data to the data argument.

occuPEN fits the standard occupancy model based on zero-inflated binomial models (MacKenzie et al. 2006, Royle and Dorazio 2008) using the penalized likelihood methods described in Hutchinson et al. (2015). See [occu](#) for model details. occuPEN returns parameter estimates that maximize a penalized likelihood in which the penalty is specified by the pen.type argument. The penalty function is weighted by lambda.

The MPLE method includes an equation for computing lambda (Moreno & Lele, 2010). If the value supplied does not equal match the one computed with this equation, the supplied value is used anyway (with a warning).

Value

unmarkedFitOccuPEN object describing the model fit.

occuPEN_CV | *Fit the MacKenzie et al. (2002) Occupancy Model with the penalized likelihood methods of Hutchinson et al. (2015) using cross-validation*

Description

This function fits the occupancy model of MacKenzie et al (2002) with the penalized methods of Hutchinson et al (2015) using k-fold cross-validation to choose the penalty weight.

Usage

```
occuPEN_CV(formula, data, knownOcc=numeric(0), starts, method="BFGS",
    engine=c("C", "R"), lambdaVec=c(0,2^seq(-4,4)),
    pen.type = c("Bayes","Ridge"), k = 5, foldAssignments = NA,
    ...)
```

Arguments

formula	Double right-hand side formula describing covariates of detection and occupancy in that order.
data	An [unmarkedFrameOccu](#) object
knownOcc	Vector of sites that are known to be occupied. These should be supplied as row numbers of the y matrix, eg, c(3,8) if sites 3 and 8 were known to be occupied a priori.
starts	Vector of parameter starting values.
method	Optimization method used by [optim](#).
engine	Either "C" or "R" to use fast C++ code or native R code during the optimization.
lambdaVec	Vector of values to try for lambda.
pen.type	Which form of penalty to use.
k	Number of folds for k-fold cross-validation.
foldAssignments	
	Vector containing the number of the fold that each site falls into. Length of the vector should be equal to the number of sites, and the vector should contain k unique values. E.g. for 9 sites and 3 folds, c(1,2,3,1,2,3,1,2,3) or c(1,1,1,2,2,2,3,3,3).
...	Additional arguments to optim, such as lower and upper bounds

Details

See [unmarkedFrame](#) and [unmarkedFrameOccu](#) for a description of how to supply data to the data argument.

This function wraps k-fold cross-validation around occuPEN_CV for the "Bayes" and "Ridge" penalties of Hutchinson et al. (2015). The user may specify the number of folds (k), the values to try (lambdaVec), and the assignments of sites to folds (foldAssignments). If foldAssignments is not provided, the assignments are done pseudo-randomly, and the function attempts to put some sites with and without positive detections in each fold. This randomness introduces variability into the results of this function across runs; to eliminate the randomness, supply foldAssignments.

Value

unmarkedFitOccuPEN_CV object describing the model fit.

occuRN   *Fit the occupancy model of Royle and Nichols (2003)*

Description

Fit the occupancy model of Royle and Nichols (2003), which relates probability of detection of the species to the number of individuals available for detection at each site. Probability of occupancy is a derived parameter: the probability that at least one individual is available for detection at the site.

Usage

```
occuRN(formula, data, K=25, starts, method="BFGS", se=TRUE,
             engine=c("C","R"), threads=1, ...)
```

Arguments

formula	double right-hand side formula describing covariates of detection and abundance, in that order.
data	Object of class [unmarkedFrameOccu](#) supplying data to the model.
K	the upper summation index used to numerically integrate out the latent abundance. This should be set high enough so that it does not affect the parameter estimates. Computation time will increase with K.
starts	initial values for the optimization.
method	Optimization method used by [optim](#).
se	logical specifying whether or not to compute standard errors.
engine	Either "C" to use fast C++ code or "R" to use native R code during the optimization.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

This function fits the latent abundance mixture model described in Royle and Nichols (2003).

The number of animals available for detection at site i is modelled as Poisson:

$$N_i \sim Poisson(\lambda_i)$$

We assume that all individuals at site i during sample j have identical detection probabilities, r_{ij}, and that detections are independent. The species will be recorded if at least one individual is detected. Thus, the detection probability for the species is linked to the detection probability for an individual by

$$p_{ij} = 1 - (1 - r_{ij})^{N_i}$$

Note that if $N_i = 0$, then $p_{ij} = 0$, and increasing values of N_i lead to higher values of p_{ij} The equation for the detection history is then:

$$y_{ij} \sim Bernoulli(p_{ij})$$

Covariates of λ_i are modelled with the log link and covariates of r_{ij} are modelled with the logit link.

Value

unmarkedFit object describing the model fit.

occuTTD   *Fit Single-Season and Dynamic Time-to-detection Occupancy Models*

Description

Fit time-to-detection occupancy models of Garrard et al. (2008, 2013), either single-season or dynamic. Time-to-detection can be modeled with either an exponential or Weibull distribution.

Usage

```
occuTTD(psiformula= ~1, gammaformula =  ~ 1, epsilonformula = ~ 1,
    detformula = ~ 1, data, ttdDist = c("exp", "weibull"),
    linkPsi = c("logit", "cloglog"), starts, method="BFGS", se=TRUE,
    engine = c("C", "R"), ...)
```

Arguments

psiformula	Right-hand sided formula for the initial probability of occupancy at each site.
gammaformula	Right-hand sided formula for colonization probability.
epsilonformula	Right-hand sided formula for extinction probability.
detformula	Right-hand sided formula for mean time-to-detection.
data	unmarkedFrameOccuTTD object that supplies the data (see unmarkedFrameOccuTTD).
ttdDist	Distribution to use for time-to-detection; either "exp" for the exponential, or "weibull" for the Weibull, which adds an additional shape parameter k.
linkPsi	Link function for the occupancy model. Options are "logit" for the standard occupancy model or "cloglog" for the complimentary log-log link, which relates occupancy to site-level abundance.
starts	optionally, initial values for parameters in the optimization.
method	Optimization method used by optim.
se	logical specifying whether or not to compute standard errors.
engine	Either "C" or "R" to use fast C++ code or native R code during the optimization.
...	Additional arguments to optim, such as lower and upper bounds

Details

Estimates site occupancy and detection probability from time-to-detection (TTD) data, e.g. time to first detection of a particular bird species during a point count or time-to-detection of a plant species while searching a quadrat (Garrard et al. 2008). Time-to-detection can be modeled as an exponential (ttdDist="exp") or Weibull (ttdDist="weibull") random variable with rate parameter λ and, for the Weibull, an additional shape parameter k. Note that occuTTD puts covariates on λ and not $1/\lambda$, i.e., the expected time between events.

In the case where there are no detections before the maximum sample time at a site (surveyLength) is reached, we are not sure if the site is unoccupied or if we just didn't wait long enough for a detection. We therefore must censor the exponential or Weibull distribution at the maximum survey length, $Tmax$. Thus, assuming true site occupancy at site i is z_i, an exponential distribution for the TTD y_i, and that $d_i = 1$ indicates y_i is censored (Kery and Royle 2016):

$$d_i = z_i * I(y_i > Tmax_i) + (1 - z_i)$$

and

$$y_i|z_i \sim Exponential(\lambda_i), d_i = 0$$

$$y_i|z_i = Missing, d_i = 1$$

Because in unmarked values of NA are typically used to indicate missing values that were a result of the sampling structure (e.g., lost data), we indicate a censored y_i in occuTTD instead by setting $y_i = Tmax_i$ in the y matrix provided to unmarkedFrameOccuTTD. You can provide either a single value of $Tmax$ to the surveyLength argument of unmarkedFrameOccuTTD, or provide a matrix, potentially with a unique value of $Tmax$ for each value of y. Note that in the latter case the value

of y that will be interpreted by occuTTD as a censored observation (i.e., $Tmax$) will differ between observations!

Occupancy and detection can be estimated with only a single survey per site, unlike a traditional occupancy model that requires at least two replicated surveys at at least some sites. However, occuTTD also supports multiple surveys per site using the model described in Garrard et al. (2013). Furthermore, multi-season dynamic models are supported, using the same basic structure as for standard occupancy models (see [colext](#)).

When linkPsi = "cloglog", the complimentary log-log link function is used for psi instead of the logit link. The cloglog link relates occupancy probability to the intensity parameter of an underlying Poisson process (Kery and Royle 2016). Thus, if abundance at a site is can be modeled as $N_i \, Poisson(\lambda_i)$, where $log(\lambda_i) = \alpha + \beta * x$, then presence/absence data at the site can be modeled as $Z_i \, Binomial(\psi_i)$ where $cloglog(\psi_i) = \alpha + \beta * x$.

Value

unmarkedFitOccuTTD object describing model fit.

optimizePenalty-methods

Identify Optimal Penalty Parameter Value

Description

Identify the optimal value of the penalty term for unmarked models that support penalized like-lihood. For each potential value of the penalty term, K-fold cross validation is performed. Log-

likelihoods for the test data in each fold are calculated and summed. The penalty term that maximizes the sum of the fold log-likelihoods is selected as the optimal value. Finally, the model is re-fit with the full dataset using the selected penalty term. Right now only Bayes-inspired penalty of Hutchinson et al. (2015) is supported.

Currently the only fitting function that supports `optimizePenalty` is `occuMulti` for multispecies occupancy modeling; see Clipp et al. (2021).

Usage

```
## S4 method for signature 'unmarkedFitOccuMulti'
optimizePenalty(
  object, penalties = c(0, 2^seq(-4, 4)), k = 5, boot = 30, ...)
```

Arguments

object	A fitted model inheriting class `unmarkedFit`
penalties	Vector of possible penalty values, all of which must be >= 0
k	Number of folds to use for k-fold cross validation
boot	Number of bootstrap samples to use to generate the variance-covariance matrix for the final model.
...	Other arguments, currently ignored

Value

`unmarkedFit` object of same type as input, with the optimal penalty value applied.

parboot   *Parametric bootstrap for* unmarked *models*

Description

Simulate datasets from a fitted model, refit the model, and generate a sampling distribution for a user-specified fit-statistic.

Usage

```
## S4 method for signature 'unmarkedFit'
parboot(object, statistic = SSE, nsim = 10,
                              report, parallel = FALSE, ncores, ...)
```

Arguments

`object`	a fitted model inheriting class "unmarkedFit"
`statistic`	a function returning a vector of fit-statistics. First argument must be the fitted model. Default is sum of squared residuals.
`nsim`	number of bootstrap replicates
`report`	Non-functional; will be removed soon.
`parallel`	logical (default = TRUE) indicating whether to compute bootstrap on multiple cores, if present. If TRUE, suppresses reporting of bootstrapped statistics. Defaults to serial calculation when nsim < 100. Parallel computation is likely to be slower for simple models when nsim < ~500, but should speed up the bootstrap of more complicated models.
`ncores`	integer (default = one less than number of available cores) number of cores to use when bootstrapping in parallel.
`...`	Additional arguments to be passed to `statistic`

Details

This function simulates datasets based upon a fitted model, refits the model, and evaluates a user-specified fit-statistic for each simulation. Comparing this sampling distribution to the observed statistic provides a means of evaluating goodness-of-fit or assessing uncertainty in a quantity of interest.

Value

An object of class `parboot` with three slots:

`call`	parboot call
`t0`	Numeric vector of statistics for original fitted model.
`t.star`	nsim by length(t0) matrix of statistics for each simulation fit.

pcount   *Fit the N-mixture model of Royle (2004)*

Description

Fit the N-mixture model of Royle (2004)

Usage

```
pcount(formula, data, K, mixture=c("P", "NB", "ZIP"),
    starts, method="BFGS", se=TRUE, engine=c("C", "R", "TMB"), threads=1, ...)
```

Arguments

formula	Double right-hand side formula describing covariates of detection and abundance, in that order
data	an unmarkedFramePCount object supplying data to the model.
K	Integer upper index of integration for N-mixture. This should be set high enough so that it does not affect the parameter estimates. Note that computation time will increase with K.
mixture	character specifying mixture: "P", "NB", or "ZIP".
starts	vector of starting values
method	Optimization method used by [optim]().
se	logical specifying whether or not to compute standard errors.
engine	Either "C", "R", or "TMB" to use fast C++ code, native R code, or TMB (required for random effects) during the optimization.
threads	Set the number of threads to use for optimization in C++, if OpenMP is available on your system. Increasing the number of threads may speed up optimization in some cases by running the likelihood calculation in parallel. If threads=1 (the default), OpenMP is disabled.
...	Additional arguments to optim, such as lower and upper bounds

Details

This function fits N-mixture model of Royle (2004) to spatially replicated count data.

See [unmarkedFramePCount]() for a description of how to format data for pcount.

This function fits the latent N-mixture model for point count data (Royle 2004, Kery et al 2005).

The latent abundance distribution, $f(N|\theta)$ can be set as a Poisson, negative binomial, or zero-inflated Poisson random variable, depending on the setting of the mixture argument, mixture = "P", mixture = "NB", mixture = "ZIP" respectively. For the first two distributions, the mean of N_i is λ_i. If $N_i \sim NB$, then an additional parameter, α, describes dispersion (lower α implies higher variance). For the ZIP distribution, the mean is $\lambda_i(1 - \psi)$, where psi is the zero-inflation parameter.

The detection process is modeled as binomial: $y_{ij} \sim Binomial(N_i, p_{ij})$.

Covariates of λ_i use the log link and covariates of p_{ij} use the logit link.

Value

unmarkedFit object describing the model fit.

pcount.spHDS	*Fit spatial hierarchical distance sampling model.*

Description

Function fits an N-mixture model for a discrete state space with raster covariates, and a detection function which decreases with distance from the observer, assumed to be at the centre. See Kery & Royle (2016) Section 9.8.4 for details.

Usage

```
pcount.spHDS(formula, data, K, mixture = c("P", "NB", "ZIP"), starts,
  method = "BFGS", se = TRUE, ...)
```

Arguments

formula	Double right-hand side formula describing covariates of detection and abundance, in that order.
	Detection model should be specified without an intercept, for example: `~ -1 + I(dist^2)`, where dist is a covariate giving the distance of each cell of the raster from the observer. Internally this forces the intercept p(0) = 1, conventional for distance sampling models (see Kery & Royle (2016) for explanation). More general models work but may not honor that constraint. e.g., `~ 1,~ dist,~ I(dist^2),~ dist + I(dist^2)`
data	an unmarkedFramePCount object supplying data to the model.
K	Integer upper index of integration for N-mixture. This should be set high enough so that it does not affect the parameter estimates. Note that computation time will increase with K.
mixture	character specifying mixture: Poisson (P), Negative-Binomial (NB), or Zero Inflated Poisson (ZIP).
starts	vector of starting values
method	Optimization method used by optim.
se	logical specifying whether or not to compute standard errors.
...	Additional arguments to optim, such as lower and upper bounds

Value

unmarkedFit object describing the model fit.

Examples

```
## Simulate some data to analyse
# This is based on Kery and Royle (2016) section 9.8.3
# See AHMbook::sim.spatialDS for more simulation options.

# We will simulate distance data for a logit detection function with sigma = 1,
# for a 6x6 square, divided into a 30 x 30 grid of pixels (900 in all), with the
# observer in the centre.

set.seed(2017)

## 1. Create coordinates for 30 x 30 grid
grx <- seq(0.1, 5.9, 0.2)    # mid-point coordinates
gr <- expand.grid(grx, grx)  # data frame with coordinates of pixel centres

## 2a. Simulate spatially correlated Habitat covariate
# Get the pair-wise distances between pixel centres
tmp <- as.matrix(dist(gr))  # a 900 x 900 matrix
# Correlation is a negative exponential function of distance, with scale parameter = 1
V <- exp(-tmp/1)
Habitat <- crossprod(t(chol(V)), rnorm(900))

## 2b. Do a detection covariate: the distance of each pixel centre from the observer
dist <- sqrt((gr[,1]-3)^2 + (gr[,2]-3)^2)

## 3. Simulate the true population
# Probability that an animal is in a pixel depends on the Habitat covariate, with
#   coefficient beta:
beta <- 1
probs <- exp(beta*Habitat) / sum(exp(beta*Habitat))
# Allocate 600 animals to the 900 pixels, get the pixel ID for each animal
pixel.id <- sample(1:900, 600, replace=TRUE, prob=probs)

## 4. Simulate the detection process
# Get the distance of each animal from the observer
# (As an approximation, we'll treat animals as if they are at the pixel centre.)
d <- dist[pixel.id]
# Calculate probability of detection with logit detection function with
sigma <- 1
p <- 2*plogis(-d^2/(2*sigma^2))
```

```
# Simulate the 1/0 detection/nondetection vector
y <- rbinom(600, 1, p)
# Check the number of animals detected
sum(y)
# Select the pixel IDs for the animals detected and count the number in each pixel
detected.pixel.id <- pixel.id[y == 1]
pixel.count <- tabulate(detected.pixel.id, nbins=900)

## 5. Prepare the data for unmarked
# Centre the Habitat covariate
Habitat <- Habitat - mean(Habitat)
# Construct the unmarkedFramePCount object
umf <- unmarkedFramePCount(y=cbind(pixel.count),     # y needs to be a 1-column matrix
    siteCovs=data.frame(dist=dist, Habitat=Habitat))
summary(umf)

## 6. Fit some models
(fm0 <- pcount.spHDS(~ -1 + I(dist^2) ~ 1, umf, K = 20))
(fm1 <- pcount.spHDS(~ -1 + I(dist^2) ~ Habitat, umf, K = 20))
# The true Habitat coefficient (beta above) = 1
# fm1 has much lower AIC; look at the population estimate
sum(predict(fm1, type="state")[, 1])
```

---

pcountOpen   *Fit the open N-mixture models of Dail and Madsen (2011) and Hostetler and Chandler (2015)*

Description

Fit the models of Dail and Madsen (2011) and Hostetler and Chandler (in press), which are generalized forms of the Royle (2004) N-mixture model for open populations.

Usage

```
pcountOpen(lambdaformula, gammaformula, omegaformula, pformula,
  data, mixture = c("P", "NB", "ZIP"), K, dynamics=c("constant", "autoreg",
  "notrend", "trend", "ricker", "gompertz"), fix=c("none", "gamma", "omega"),
  starts, method = "BFGS", se = TRUE, immigration = FALSE,
  iotaformula = ~1, ...)
```

Arguments

lambdaformula	Right-hand sided formula for initial abundance
gammaformula	Right-hand sided formula for recruitment rate (when dynamics is "constant", "autoreg", or "notrend") or population growth rate (when dynamics is "trend", "ricker", or "gompertz")
omegaformula	Right-hand sided formula for apparent survival probability (when dynamics is "constant", "autoreg", or "notrend") or equilibrium abundance (when dynamics is "ricker" or "gompertz")

pformula	Right-hand sided formula for detection probability
data	An object of class [unmarkedFramePCO](). See details
mixture	character specifying mixture: "P", "NB", or "ZIP" for the Poisson, negative binomial, and zero-inflated Poisson distributions.
K	Integer defining upper bound of discrete integration. This should be higher than the maximum observed count and high enough that it does not affect the parameter estimates. However, the higher the value the slower the compuatation.
dynamics	Character string describing the type of population dynamics. "constant" indicates that there is no relationship between omega and gamma. "autoreg" is an auto-regressive model in which recruitment is modeled as gamma*N[i,t-1]. "notrend" model gamma as lambda*(1-omega) such that there is no temporal trend. "trend" is a model for exponential growth, N[i,t] = N[i,t-1]*gamma, where gamma in this case is finite rate of increase (normally referred to as lambda). "ricker" and "gompertz" are models for density-dependent population growth. "ricker" is the Ricker-logistic model, N[i,t] = N[i,t-1]*exp(gamma*(1-N[i,t-1]/omega)), where gamma is the maximum instantaneous population growth rate (normally referred to as r) and omega is the equilibrium abundance (normally referred to as K). "gompertz" is a modified version of the Gompertz-logistic model, N[i,t] = N[i,t-1]*exp(gamma*(1-log(N[i,t-1]+1)/log(omega+1))), where the interpretations of gamma and omega are similar to in the Ricker model.
fix	If "omega", omega is fixed at 1. If "gamma", gamma is fixed at 0.
starts	vector of starting values
method	Optimization method used by [optim]().
se	logical specifying whether or not to compute standard errors.
immigration	logical specifying whether or not to include an immigration term (iota) in population dynamics.
iotaformula	Right-hand sided formula for average number of immigrants to a site per time step
...	additional arguments to be passed to [optim]().

Details

These models generalize the Royle (2004) N-mixture model by relaxing the closure assumption. The models include two or three additional parameters: gamma, either the recruitment rate (births and immigrations), the finite rate of increase, or the maximum instantaneous rate of increase; omega, either the apparent survival rate (deaths and emigrations) or the equilibrium abundance (carrying capacity); and iota, the number of immigrants per site and year. Estimates of population size at each time period can be derived from these parameters, and thus so can trend estimates. Or, trend can be estimated directly using dynamics="trend".

When immigration is set to FALSE (the default), iota is not modeled. When immigration is set to TRUE and dynamics is set to "autoreg", the model will separately estimate birth rate (gamma) and number of immigrants (iota). When immigration is set to TRUE and dynamics is set to "trend", "ricker", or "gompertz", the model will separately estimate local contributions to population growth (gamma and omega) and number of immigrants (iota).

The latent abundance distribution, $f(N|\theta)$ can be set as a Poisson, negative binomial, or zero-inflated Poisson random variable, depending on the setting of the mixture argument, mixture = "P", mixture = "NB", mixture = "ZIP" respectively. For the first two distributions, the mean of N_i is λ_i. If $N_i \sim NB$, then an additional parameter, α, describes dispersion (lower α implies higher variance). For the ZIP distribution, the mean is $\lambda_i(1-\psi)$, where psi is the zero-inflation parameter.

For "constant", "autoreg", or "notrend" dynamics, the latent abundance state following the initial sampling period arises from a Markovian process in which survivors are modeled as $S_{it} \sim Binomial(N_{it-1}, \omega_{it})$, and recruits follow $G_{it} \sim Poisson(\gamma_{it})$. Alternative population dynamics can be specified using the dynamics and immigration arguments.

The detection process is modeled as binomial: $y_{ijt} \sim Binomial(N_{it}, p_{ijt})$.

λ_i, γ_{it}, and ι_{it} are modeled using the the log link. p_{ijt} is modeled using the logit link. ω_{it} is either modeled using the logit link (for "constant", "autoreg", or "notrend" dynamics) or the log link (for "ricker" or "gompertz" dynamics). For "trend" dynamics, ω_{it} is not modeled.

Value

An object of class unmarkedFitPCO.

Warning

This function can be extremely slow, especially if there are covariates of gamma or omega. Consider testing the timing on a small subset of the data, perhaps with se=FALSE. Finding the lowest value of K that does not affect estimates will also help with speed.

Note

When gamma or omega are modeled using year-specific covariates, the covariate data for the final year will be ignored; however, they must be supplied.

If the time gap between primary periods is not constant, an M by T matrix of integers should be supplied to unmarkedFramePCO using the primaryPeriod argument.

Secondary sampling periods are optional, but can greatly improve the precision of the estimates.

piFuns   *Compute multinomial cell probabilities*

Description

Compute the cell probabilities used in the multinomial-Poisson models multinomPois and gmult-mix. These functions use piFuns *internally* to calculate multinomial likelihoods from the occasion-wise detection probabilities. The only reason to call them directly is to check their behaviour.

Usage

```
removalPiFun(p)
doublePiFun(p)
```

Arguments

p   matrix of detection probabilities at each site for each observation

Details

These two functions are provided as examples of possible functions to calculate multinomial cell probabilities. Users may write their own functions for specific sampling designs (see the example).

Value

For removalPiFun, a matrix of cell probabilities for each site and sampling period.

For doublePiFun, a matrix of cell probabilities for each site and observer combination. Column one is probability observer 1 but not observer 2 detects the object, column two is probability that observer 2 but not observer 1 detects the object, and column 3 is probability of both detecting.

See Also

makePiFuns for factory functions to create customised piFuns.

Examples

```
(pRem <- matrix(0.5, nrow=3, ncol=3)) # Capture probabilities
removalPiFun(pRem) # Cell probs

(pDouble <- matrix(0.5, 3, 2)) # Observer detection probs
doublePiFun(pDouble) # Cell probs

# A user-defined piFun calculating removal probs when time intervals differ.
# Here 10-minute counts were divided into 2, 3, and 5 minute intervals.
# This function could be supplied to unmarkedFrameMPois along with the obsToY
# argument shown below.

instRemPiFun <- function(p) {
M <- nrow(p)
J <- ncol(p)
pi <- matrix(NA, M, J)
p[,1] <- pi[,1] <- 1 - (1 - p[,1])^2
p[,2] <- 1 - (1 - p[,2])^3
p[,3] <- 1 - (1 - p[,3])^5
for(i in 2:J) {
pi[,i] <- pi[, i - 1]/p[, i - 1] * (1 - p[, i - 1]) * p[, i]
}
return(pi)
}

instRemPiFun(pRem)

# Associated obsToY matrix required by unmarkedFrameMPois
o2y <- diag(3) # if y has 3 columns
o2y[upper.tri(o2y)] <- 1
o2y
```

---

plotEffects   *Plot marginal effects of covariates in unmarked models*

Description

This function generates a plot visualizing the effects of a single covariate on a parameter (e.g. occupancy, abundance) in an unmarked model. If the covariate is numeric, the result is a line plot with an error ribbon where the x-axis is the range of the covariate and the y-axis is the predicted parameter value. If the covariate is an R factor (i.e., categorical), the x-axis instead contains each unique value of the covariate.

All covariates in the model besides the one being plotted are held either at their median value (if they are numeric) or at their reference level (if they are factors).

Some types of unmarked models may require additional arguments, which are passed to the matching predict method. For example, unmarkedFitOccuMulti models require the species argument to be included in the function call in order to work properly.

If you want to customize a plot, the easiest approach is to get data formatted for plotting using `plotEffectsData`, and use that. If you want to see and/or modify the code used by `plotEffects` to generate the default plots, run `getMethod("plotEffects", "unmarkedFit")` in the R console.

Usage

```
## S4 method for signature 'unmarkedFit'
plotEffects(object, type, covariate, level=0.95, ...)
## S4 method for signature 'unmarkedFit'
plotEffectsData(object, type, covariate, level=0.95, ...)
```

Arguments

`object`	A fitted model inheriting class `unmarkedFit`
`type`	Submodel in which the covariate of interest can be found, for example `"state"` or `"det"`. This will depend on the fitted model
`covariate`	The name of the covariate to be plotted, as a character string
`level`	Confidence level for the error ribbons or bars
`...`	Other arguments passed to the `predict` function, required for some `unmarkedFit` types such as `unmarkedFitOccuMulti`

Value

A plot (`plotEffects` or a data frame (`plotEffectsData`) containing values to be used in a plot.

Author(s)

Ken Kellner <contact@kenkellner.com>

Examples

```
## Not run:

# Simulate data and build an unmarked frame
set.seed(123)
dat_occ <- data.frame(x1=rnorm(500))
dat_p <- data.frame(x2=rnorm(500*5))

y <- matrix(NA, 500, 5)
z <- rep(NA, 500)

b <- c(0.4, -0.5, 0.3, 0.5)

re_fac <- factor(sample(letters[1:5], 500, replace=T))
dat_occ$group <- re_fac

re_idx <- as.numeric(re_fac)

idx <- 1
for (i in 1:500){
```

```
    z[i] <- rbinom(1,1, plogis(b[1] + b[2]*dat_occ$x1[i] + re[re_idx[i]]))
    for (j in 1:5){
      y[i,j] <- z[i]*rbinom(1,1,
                       plogis(b[3] + b[4]*dat_p$x2[idx]))
      idx <- idx + 1
    }
  }

  umf <- unmarkedFrameOccu(y=y, siteCovs=dat_occ, obsCovs=dat_p)

  # Fit model
  (fm <- occu(~x2 ~x1 + group, umf))

  # Plot marginal effects of various covariates
  plotEffects(fm, "state", "x1")
  plotEffects(fm, "state", "group")
  plotEffects(fm, "det", "x2")

  # Get raw data used for a plot
  plotEffectsData(fm, "state", "group")

  # See code used by plotEffects so you can edit it yourself and customize the plot
  methods::getMethod("plotEffects", "unmarkedFit")

## End(Not run)
```

---

pointtran   *Simulated point-transect data*

Description

Response matrix of animals detected in five distance classes plus two covariates.

Usage

```
data(pointtran)
```

Format

A data frame with 30 observations on the following 7 variables.

dc1 Counts in distance class 1 [0-5 m]

dc2 Counts in distance class 2 [5-10 m]

dc3 Counts in distance class 3 [10-15 m]

dc4 Counts in distance class 4 [15-20 m]

dc5 Counts in distance class 5 [20-25 m]

area a numeric vector

habitat a factor with levels A B C

Examples

```
data(pointtran)
pointtran

# Format for distsamp()
ptUMF <- with(pointtran, {
        unmarkedFrameDS(y = cbind(dc1, dc2, dc3, dc4, dc5),
        siteCovs = data.frame(area, habitat),
        dist.breaks = seq(0, 25, by=5), survey = "point", unitsIn = "m")
        })
```

---

posteriorSamples	*Draw samples from the posterior predictive distribution*

Description

Draw samples from the empirical Bayes posterior predictive distribution derived from unmarked models or ranef objects

Usage

```
## S4 method for signature 'unmarkedRanef'
posteriorSamples(object, nsims=100, ...)
## S4 method for signature 'unmarkedFit'
posteriorSamples(object, nsims=100, ...)
```

Arguments

object	An object inheriting class unmarkedRanef or unmarkedFit
nsims	Number of draws to make from the posterior predictive distribution
...	Other arguments

Value

unmarkedPostSamples object containing the draws from the posterior predictive distribution. The draws are in the @samples slot.

```

---

powerAnalysis	*Conduct a power analysis for an* unmarked *model*

Description

This function uses a simulation-based approach to estimate power for parameters in unmarked models. At a minimum, users must provide an unmarkedFrame object describing the experimental design and a list of effect sizes for each parameter in the model. See the unmarkedPower vignette for more details and examples.

Usage

```
   ## S4 method for signature 'unmarkedFrame'
powerAnalysis(object, model = NULL, effects = NULL,
    alpha=0.05, nsim = 100, parallel = FALSE, nulls=NULL, ...)
   ## S4 method for signature 'list'
powerAnalysis(object, model = NULL, effects = NULL,
    alpha=0.05, nsim = length(object), parallel = FALSE, nulls=NULL, ...)
```

Arguments

object	An unmarkedFrame object representing the desired study design. The values in the response (y) don't matter and can be missing. Alternatively, you can provide a list of such objects with the response data already simulated (such as the output from simulate).
model	The model to use when the unmarkedFrame type is used for multiple model types. For example, if the object is an unmarkedFrameOccu, model should be set to occu or occuRN.

effects	A list containing the desired effect sizes/parameter values for which you want to estimate power. This list must follow a specific format. There is one named entry in the list per submodel (e.g., occupancy, detection). Each list element should be a numeric vector with length equal to the number of parameters in that submodel. Parameter values are on the inverse link scale. You can leave `effects=NULL`, which will generate an error message with a template that you can fill in.
alpha	Desired Type I error rate.
nsim	Number of simulations to conduct.
parallel	Logical; run simulations in parallel?
nulls	If provided, a list matching the structure of `effects` which defines the null hypothesis value for each parameter. By default the null is 0 for all parameters.
...	Arguments to send to the fitting function for the model. Most importantly this will include formula argument(s), but could also include distributions, key functions, etc. For example, for simulating occupancy data, you must also supply the argument `formula = ~1~1` for a no-covariate model, `formula=~1~x` for a covariate effect of x on occupancy, etc.

Value

unmarkedPower object containing the results of the power analysis. For information on interpretation of the output, see the power analysis vignette.

umf <- unmarkedFrameOccu(y, siteCovs=sc)

# Power analysis
p <- powerAnalysis(umf, model=occu, formula=~1~x,
                   effects = list(state = c(-0.2, 0.3), det = 0))

p
summary(p, alpha=0.3)
plot(p, ylim=c(-3, 3))
```

```
plot(p, ylim=c(-3, 3))

# Simulate your own datasets first and pass to power analysis
cf <- list(state=c(0,1), det=0)
s <- simulate(umf, model = occu, formula=~1~x, coefs=cf, nsim = 100)
p2 <- powerAnalysis(s, model=occu, formula=~1~x, effects=cf)
p2

## End(Not run)
```

| predict | *Predict from fitted models and other unmarked objects* |

Description

These methods return predicted values from `unmarkedFit` objects, `fitLists`, or `ranef` output. Most object types use the same method, but some have unique options; see usage below.

Usage

```
## S4 method for signature 'unmarkedFit'
predict(object, type, newdata, backTransform = TRUE,
  na.rm = TRUE, appendData = FALSE, level = 0.95, re.form = NULL, ...)
## S4 method for signature 'unmarkedFitOccuMulti'
predict(object, type, newdata,
  level = 0.95, species = NULL, cond = NULL, nsims = 100, ...)
## S4 method for signature 'unmarkedFitOccuMS'
predict(object, type, newdata,
  level = 0.95, nsims = 100, ...)
## S4 method for signature 'unmarkedFitList'
predict(object, type, newdata = NULL,
  backTransform = TRUE, appendData = FALSE, level = 0.95)
## S4 method for signature 'unmarkedRanef'
predict(object, func, nsims = 100, ...)
```

Arguments

object	A unmarkedFit, unmarkedFitList, or unmarkedRanef object.
type	The submodel to predict values for, such as state or det. The available types depend on the model.
newdata	Optional; provide a data.frame of new covariate values to predict with. If not supplied, the original data are used.
backTransform	Logical. If TRUE, returned values are on the original (e.g. probability, abundance) scale.
na.rm	Logical. Should missing values be removed when predicting from original data?

appendData	Logical. Should covariate data used for prediction be appended to the output data frame?
level	The confidence interval to calculate. For example `0.95` results in lower and upper bounds for a 95% confidence interval. If set to `NULL`, no SE or confidence intervals will be returned.
re.form	For `unmarkedFit` types that support random effects, should the random effects be included in the prediction? If `NULL`, they will be, if `NA`, they will not be.
species	Which species (integer or species name as a string) should predictions be calculated for? For `unmarkedFitOccuMulti` only. If multiple species are provided, the co-occurence probability is returned. See [occuMulti](#).
cond	Which species (integer or species name as a string) should predictions be calculated conditional on? If conditional on species presence, supply just the species name; if species absence, put a minus sign in front of the species name, e.g. "-coyote". See [occuMulti](#).
nsims	Number of bootstrap simulations to use. Relevant only for some predict types.
func	A function to apply to bootstrapped `unmarkedRanef` samples; see details.
...	Other arguments, currently ignored

Details

The `predict` method for unmarkedRanef objects generates the empirical Bayes posterior predictive distribution for functions of the random variables (latent abundance or occurrence).

In addition to the output object from ranef, you must also supply a custom function to argument func. The function must take as input a matrix with dimensions M x T, where M is the number of sites and T is the number of primary periods (T=1 for single-season models). The output of this function should be a vector or matrix containing the derived parameters of interest.

You may also manually set the number of draws from the posterior predictive distribution with argument nsims; the default is 100.

The output of `predict` will be a vector or array with one more dimension than the output of the function supplied func, corresponding to the number of draws requested nsims. For example, if func outputs a scalar, the output of predict will be a vector with length equal to nsims. If func outputs a 3x2 matrix, the output of predict will be an array with dimensions 3x2xnsims. See [ranef](#) for an example.

Alternatively, you can use the [posteriorSamples](#) function on the ranef output object to obtain the full posterior predictive distribution. This is useful if you are having trouble designing your custom function or if you want to obtain multiple different derived parameters from the same posterior predictive distribution.

Value

For most methods, a `data.frame` with four columns: the predicted values, standard errors, and lower and upper bounds. If `appendData = TRUE` covariate data are also in the output. For `unmarkedRanef`, an array is returned. See details.

---

randomTerms *Extract estimates of random effect terms*

Description

Extract estimates and summary statistics of random effect terms from an `unmarkedFit` model or an `unmarkedEstimate`.

Usage

```
## S4 method for signature 'unmarkedEstimate'
randomTerms(object, level=0.95, addMean = FALSE, ...)
## S4 method for signature 'unmarkedFit'
randomTerms(object, type, level=0.95, addMean = FALSE, ...)
```

Arguments

`object`	An object inheriting class `unmarkedEstimate` or `unmarkedFit`
`level`	Significance level to use for confidence interval
`type`	If provided, return only random effect terms from the chosen submodel type (as a character string)
`addMean`	Logical. Should the corresponding mean intercept or slope (if any) be added to the value of the random effect (yielding the complete random intercept/slope)?
`...`	Other arguments

Value

`data.frame` containing estimates, SEs, and confidence intervals for random effect terms in the model.

Author(s)

Ken Kellner <contact@kenkellner.com>

---

ranef *Estimate posterior distributions of latent occupancy or abundance*

Description

Estimate posterior distributions of the random variables (latent occupancy or abundance) using empirical Bayes methods. These methods return an object storing the posterior distributions of the latent variables at each site, and for each year (primary period) in the case of open population models. See unmarkedRanef-class and posteriorSamples for methods used to manipulate the returned object.

Usage

```
## S4 method for signature 'unmarkedFit'
ranef(object, ...)
```

Arguments

object   A unmarkedFit object

...   Other arguments. For some abundance models you can specify K; for multi-
                species models you can specify species.

Warning

Empirical Bayes methods can underestimate the variance of the posterior distribution because they
do not account for uncertainty in the hyperparameters (lambda or psi). Eventually, we hope to add
methods to account for the uncertainty of the hyperparameters.

Note also that the posterior mode appears to exhibit some bias as an estimator or abundance. Con-
sider using the posterior mean instead, even though it will not be an integer in general. More
simulation studies are needed to evaluate the performance of empirical Bayes methods for these
models.

Note

From Carlin and Louis (1996): "... the Bayesian approach to inference depends on a prior distri-
bution for the model parameters. This prior can depend on unknown parameters which in turn may
follow some second-stage prior. This sequence of parameters and priors consitutes a hierarchical
model. The hierarchy must stop at some point, with all remaining prior parameters assumed known.
Rather than make this assumption, the basic empirical Bayes approach uses the observed data to es-
timate these final stage parameters (or to estimate the Bayes rule), and proceeds as in a standard
Bayesian analysis."

```

---

residuals   *Calculate residuals from a model*

Description

Calculates residuals from a model. The approach varies based on the model type, but is usually the observed data (y) minus the fitted values. See `fitted`.

Usage

```
## S4 method for signature 'unmarkedFit'
residuals(object, ...)
```

Arguments

object   A unmarkedFit object

...   Other arguments, currently unused.

Value

In most cases, `residuals` returns a matrix of residual values with the same dimensions as the y matrix (M x J or M x JT). For some models with multiple observation processes or multiple species, such as `gdistremoval` or `occuMulti`, the output may be a named list of matrices.

---

richness   *Estimate posterior distributions of site richness*

Description

Estimate posterior distributions of site richness from a fitted community occupancy model using empirical Bayes methods. This function uses [ranef](#) and [posteriorSamples](#) internally.

Usage

```
## S4 method for signature 'unmarkedFitOccuComm'
richness(object, nsims=100, posterior=FALSE)
```

Arguments

object	A unmarkedFitOccuComm object.
nsims	Number of posterior samples to generate.
posterior	Logical. If FALSE mean estimates for each site are returned; if TRUE the entire posterior for each site is returned.

Author(s)

Ken Kellner <contact@kenkellner.com>

SE-methods   *Methods for Function SE in Package 'unmarked'*

Description

Extract standard errors of parameter estimates from a fitted model.

Methods

obj = "linCombOrBackTrans" A model prediction

obj = "unmarkedEstimate" See [unmarkedEstimate-class](#)

obj = "unmarkedFit" A fitted model

---

shinyPower *Launch a Shiny app to help with power analysis*

Description

Launch a Shiny app to test power under various scenarios. Requires the Shiny package to be installed.

Usage

```
shinyPower(object, ...)
```

Arguments

object	A template `unmarkedFit` object; see documentation for `powerAnalysis` for details on how to create this
...	Currently ignored

Value

No return value, called for its side effects.

---

sight2perpdist *Convert sight distance and sight angle to perpendicular distance.*

Description

When distance data are collected on line transects using sight distances and sight angles, they need to be converted to perpendicular distances before analysis.

Usage

```
sight2perpdist(sightdist, sightangle)
```

Arguments

sightdist	Distance from observer
sightangle	Angle from center line. In degrees between 0 and 180.

Value

Perpendicular distance

See Also

[distsamp](#)

Examples

```
round(sight2perpdist(10, c(0, 45, 90, 135, 180)))
```

---

sigma   *Extract estimates of random effect standard deviations*

Description

Extract estimates and summary statistics of random effect standard deviations from an unmarkedFit model or an unmarkedEstimate.

Usage

```
## S4 method for signature 'unmarkedEstimate'
sigma(object, level=0.95, ...)
## S4 method for signature 'unmarkedFit'
sigma(object, type, level=0.95, ...)
```

Arguments

object	An object inheriting class unmarkedEstimate or unmarkedFit
level	Significance level to use for confidence interval
type	If provided, return only random effect SDs from the chosen submodel type (as a character string)
...	Other arguments

Value

data.frame containing estimates, SEs, and confidence intervals for random effect standard deviations in the model.

Author(s)

Ken Kellner <contact@kenkellner.com>

---

simulate   *Simulate datasets from any* unmarked *model type*

Description

Simulate data from a fitted model, or simulate an entirely new dataset from a study design defined by an unmarkedFrame.

Usage

```
## S4 method for signature 'unmarkedFit'
simulate(object, nsim=1, seed=NULL, ...)
## S4 method for signature 'unmarkedFrame'
simulate(object, nsim=1, seed=NULL, model = NULL,
                              coefs = NULL, quiet = FALSE, ...)
```

Arguments

object	Fitted model or unmarkedFrame.
nsim	Number of simulations
seed	Ignored
model	The model to use when object is an unmarkedFrame used for multiple model types. For example, if the object is an unmarkedFrameOccu, model should be set to occu or occuRN.
coefs	List with one element per submodel. Each list element should be named with the corresponding submodel, and should be a numeric vector of parameter values to use for that submodel when simulating the dataset. Note that parameter values should be on the inverse link scale. The number of parameter values in the vector depends on the model specified, covariates, etc. If you are not sure how to specify this list, set coefs = NULL and the function will return the correct structure.
quiet	If TRUE, don't print informational messages.
...	Used only for the unmarkedFrame method. Arguments to send to the corresponding fitting function. Most importantly this will include formula arguments, but could also include distributions, key functions, etc. For example, for simulating occupancy data, you must also supply the argument formula = ~1~1 for a no-covariate model, formula=~1~x for a covariate effect of x on occupancy, etc. See examples below.

Examples

```
## Not run:

# Simulation of an occupancy dataset from scratch

# First create an unmarkedFrame with the correct design
```

```
M <- 300 # number of sites
J <- 5   # number of occasions

# The values in the y-matrix don't matter as they will be simulated
# We can supply them as all NAs
y <- matrix(NA, M, J)

# Site covariate
x <- rnorm(M)

# Create unmarkedFrame
umf <- unmarkedFrameOccu(y = y, siteCovs = data.frame(x = x))

# Must specify model = occu since unmarkedFrameOccu is also used for occuRN
# the formula species the specific model structure we want to simulate
# If we don't specify coefs, unmarked will generate a template you can copy and use
simulate(umf, model = occu, formula = ~1~x)

# Now set coefs
# Here we imply a mean occupancy and mean detection of 0.5
# (corresponding to values of 0 on the inverse link scale) and a positive effect of x
s <- simulate(umf, model = occu, formula = ~1~x,
                coefs = list(state = c(0,0.3), det = 0))

head(s[[1]])

occu(~1~x, s[[1]])

# For some models we can also include a random effect
# add a factor covariate
umf@siteCovs$x2 <- factor(sample(letters[1:10], M, replace=TRUE))

# The final value in coefs now represents the random effect SD for x2
s <- simulate(umf, model = occu, formula = ~1~x+(1|x2),
                coefs = list(state = c(0,0.3, 1), det = 0))

head(s[[1]])

occu(~1~x+(1|x2), s[[1]])

# Here's a more complicated example simulating a gdistsamp dataset
# using a negative binomial distribution
M <- 100
J <- 3
T <- 2
y <- matrix(NA, M, J*T)
umf2 <- unmarkedFrameGDS(y=y,
                          siteCovs=data.frame(x=rnorm(M)),
                          dist.breaks = c(0, 10, 20, 30), unitsIn='m',
                          numPrimary = T, survey="point")

cf <- list(lambda=c(1, 0.3), phi=0, det=c(log(20), 0), alpha=log(1))
```

```
# Note we now also supply another argument mixture="NB" to ...
s2 <- simulate(umf2, coefs=cf, lambdaformula=~x, phiformula=~1, pformula=~x,
               mixture="NB")
head(s2[[1]])

gdistsamp(~x, ~1, ~x, s2[[1]], mixture="NB")

## End(Not run)
```

SSE   *Compute Sum of Squared Residuals for a Model Fit.*

Description

Compute the sum of squared residuals for an unmarked fit object. This is useful for a [parboot](#).

Usage

```
SSE(fit, ...)
```

Arguments

fit   An unmarked fit object.

...   Additional arguments to be passed to statistic

Value

A numeric value for the models SSE.

[parboot](#)

Switzerland   *Swiss landscape data*

Description

Spatially-referenced data on elevation, forest cover, and water at a 1km-sq resolution.

Usage

```
data(Switzerland)
```

Format

A data frame with 42275 observations on the following 5 variables.

x Easting (m)

y Northing (m)

elevation a numeric vector (m)

forest a numeric vector (percent cover)

water a numeric vector (percent cover)

Details

Forest and water coverage (in percent area) was computed using the 1992-97 landcover dataset of the Swiss Federal Statistical Office (http://www.bfs.admin.ch). Median elevation (in metres) was computed using a median aggregation of the digital elevation model of the Swiss Federal Statistical Office.

x and y are the coordinates of the center of each 1km2 pixel.

The coordinate reference system intentionally not specified.

These data can only be used for non-profit projects. Otherwise, written permission must be obtained from the Swiss Federal Statistical Office

Source

unmarkedEstimate-class

Class "unmarkedEstimate"

Description

Contains parameter estimates, covariance matrix, and metadata

Objects from the Class

Creating these objects is done internally not by users.

Slots

name: Object of class "character" storing parameter names

short.name: Object of class "character" storing abbreviated parameter names

estimates: Object of class "numeric"

covMat: Object of class "matrix"

covMatBS: Object of class "matrix"

fixed: Object of class "numeric"

invlink: Object of class "character"

invlinkGrad: Object of class "character"

randomVarInfo: Object of class "list"

Methods

backTransform signature(obj = "unmarkedEstimate")

coef signature(object = "unmarkedEstimate")

confint signature(object = "unmarkedEstimate")

linearComb signature(obj = "unmarkedEstimate",coefficients = "matrixOrVector")

SE signature(obj = "unmarkedEstimate")

show signature(object = "unmarkedEstimate")

vcov signature(object = "unmarkedEstimate")

Note

These methods are typically called within a call to a method for unmarkedFit-class

Examples

showClass("unmarkedEstimate")

---

unmarkedEstimateList-class
<div align="center">

Class "unmarkedEstimateList"

</div>

Description

Class to hold multiple unmarkedEstimates in an unmarkedFit

Slots

`estimates`: A `"list"` of models.

---

unmarkedFit-class   *Class "unmarkedFit"*

Description

Contains fitted model information which can be manipulated or extracted using the methods described below.

Methods

[`signature(x = "unmarkedFit", i = "ANY", j = "ANY",drop = "ANY")`: extract one of names(obj), eg 'state' or 'det'

backTransform `signature(obj = "unmarkedFit")`: back-transform parameters to original scale when no covariate effects are modeled

coef `signature(object = "unmarkedFit")`: returns parameter estimates. type can be one of names(obj), eg 'state' or 'det'. If altNames=TRUE estimate names are more specific.

confint `signature(object = "unmarkedFit")`: Returns confidence intervals. Must specify type and method (either "normal" or "profile")

getData `signature(object = "unmarkedFit")`: extracts data

getFP `signature(object = "unmarkedFit")`: calculates and extracts expected false positive detection probabilities

getB `signature(object = "unmarkedFit")`: calculates and extracts expected probabilities a true positive detection was classified as certain

linearComb `signature(obj = "unmarkedFit",coefficients = "matrixOrVector")`: Returns estimate and SE on original scale when covariates are present

names `signature(x = "unmarkedFit")`: Names of parameter levels

parboot `signature(object = "unmarkedFit")`: Parametric bootstrapping method to assess goodness-of-fit

plot `signature(x = "unmarkedFit", y = "missing")`: Plots expected vs. observed values

profile `signature(fitted = "unmarkedFit")`: used by confint method='profile'

sampleSize `signature(object = "unmarkedFit")`: returns number of sites in sample

SE `signature(obj = "unmarkedFit")`: returns standard errors

summary `signature(object = "unmarkedFit")`: results with more details

update `signature(object = "unmarkedFit")`: refit model with changes to one or more arguments

vcov `signature(object = "unmarkedFit")`: returns variance-covariance matrix

smoothed `signature(object="unmarkedFitColExt")`: Returns the smoothed trajectory from a colonization-extinction model fit. Takes additional logical argument mean which specifies whether or not to return the average over sites.

projected `signature(object="unmarkedFitColExt")`: Returns the projected trajectory from a colonization-extinction model fit. Takes additional logical argument mean which specifies whether or not to return the average over sites.

logLik `signature(object="unmarkedFit")`: Returns the log-likelihood.

LRT `signature(m1="unmarkedFit", m2="unmarkedFit")`: Returns the chi-squared statistic, degrees-of-freedom, and p-value from a Likelihood Ratio Test.

Note

This is a superclass with child classes for each fit type

Examples

```
showClass("unmarkedFit")

# Format removal data for multinomPois
data(ovendata)
ovenFrame <- unmarkedFrameMPois(y = ovendata.list$data,
siteCovs = as.data.frame(scale(ovendata.list$covariates[,-1])),
type = "removal")

# Fit a couple of models
(fm1 <- multinomPois(~ 1 ~ ufc + trba, ovenFrame))
summary(fm1)

# Apply a bunch of methods to the fitted model

# Look at the different parameter types
names(fm1)
fm1['state']
fm1['det']

# Coefficients from abundance part of the model
coef(fm1, type='state')

# Variance-covariance matrix
vcov(fm1, type='state')

# Confidence intervals using profiled likelihood
confint(fm1, type='state', method='profile')
```

```
# Expected values
fitted(fm1)

# Original data
getData(fm1)

# Detection probabilities
getP(fm1)

# log-likelihood
logLik(fm1)

# Back-transform detection probability to original scale
# backTransform only works on models with no covariates or
#     in conjunction with linearComb (next example)
backTransform(fm1, type ='det')

# Predicted abundance at specified covariate values
(lc <- linearComb(fm1, c(Int = 1, ufc = 0, trba = 0), type='state'))
backTransform(lc)

# Assess goodness-of-fit
parboot(fm1)
plot(fm1)

# Predict abundance at specified covariate values.
newdat <- data.frame(ufc = 0, trba = seq(-1, 1, length=10))
predict(fm1, type='state', newdata=newdat)

# Fit a new model without covariates
(fmNull <- update(fm1, formula = ~1 ~1))
```

---

unmarkedFitList-class   *Class "unmarkedFitList"*

Description

Class to hold multiple fitted models from one of unmarked's fitting functions

Objects from the Class

Objects can be created by using the [fitList](#) function.

Slots

fits: A "list" of models.

Methods

coef signature(object = ″unmarkedFitList″): Extract coefficients

SE signature(object = ″unmarkedFitList″): Extract standard errors

modSel signature(object = ″unmarkedFitList″): Model selection

predict signature(object = ″unmarkedFitList″): Model-averaged prediction

Note

Model-averaging regression coefficients is intentionally not implemented.

See Also

[fitList](), [unmarkedFit]()

Examples

```
showClass(″unmarkedFitList″)

data(linetran)
(dbreaksLine <- c(0, 5, 10, 15, 20))
lengths <- linetran$Length * 1000

ltUMF <- with(linetran, {
unmarkedFrameDS(y = cbind(dc1, dc2, dc3, dc4),
siteCovs = data.frame(Length, area, habitat), dist.breaks = dbreaksLine,
tlength = lengths, survey = ″line″, unitsIn = ″m″)
})

fm1 <- distsamp(~ 1 ~1, ltUMF)
fm2 <- distsamp(~ area ~1, ltUMF)
fm3 <- distsamp( ~ 1 ~area, ltUMF)

fl <- fitList(Null=fm1, A.=fm2, .A=fm3)
fl

coef(fl)
SE(fl)

ms <- modSel(fl, nullmod=″Null″)
ms
```

---

unmarkedFrame   *Create an unmarkedFrame, or one of its child classes.*

Description

Constructor for unmarkedFrames.

Usage

```
unmarkedFrame(y, siteCovs=NULL, obsCovs=NULL, obsToY)
```

Arguments

y	An MxJ matrix of the observed measured data, where M is the number of sites and J is the maximum number of observations per site.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of [data.frame](#)s of covariates that vary within sites, or a [data.frame](#) with MxJ rows in site-major order.
obsToY	optional matrix specifying relationship between observation-level covariates and response matrix

Details

unmarkedFrame is the S4 class that holds data structures to be passed to the model-fitting functions in unmarked.

An unmarkedFrame contains the observations (y), covariates measured at the observation level (obsCovs), and covariates measured at the site level (siteCovs). For a data set with M sites and J observations at each site, y is an M x J matrix. obsCovs and siteCovs are both data frames (see [data.frame](#)). siteCovs has M rows so that each row contains the covariates for the corresponding sites. obsCovs has M*obsNum rows so that each covariates is ordered by site first, then observation number. Missing values are coded with NA in any of y, siteCovs, or obsCovs.

Additionally, unmarkedFrames contain metadata: obsToY. obsToY is a matrix describing relationship between response matrix and observation-level covariates. Generally this does not need to be supplied by the user; however, it may be needed when using [multinomPois](#). For example, double observer sampling, y has 3 columns corresponding the observer 1, observer 2, and both, but there were only two independent observations. In this situation, y has 3 columns, but obsToY must be specified.

Several child classes of unmarkedFrame require addional metadata. For example, unmarkedFrameDS is used to organize distsance sampling data for the [distsamp](#) function, and it has arguments dist.breaks, tlength, survey, and unitsIn, which specify the distance interval cut points, transect lengths, "line" or "point" transect, and units of measure, respectively.

All site-level covariates are automatically copied to obsCovs so that site level covariates are available at the observation level.

Value

an unmarkedFrame object

summary(frogUMF)

## End(Not run)
```

---

unmarkedFrame-class   *Class "unmarkedFrame"*

Description

Methods for manipulating, summarizing and viewing unmarkedFrames

Objects from the Class

Objects can be created by calls to the constructor function [unmarkedFrame](). These objects are passed to the data argument of the fitting functions.

Slots

y: Object of class "matrix"

obsCovs: Object of class "optionalDataFrame"

siteCovs: Object of class "optionalDataFrame"

obsToY: Object of class "optionalMatrix"

Methods

[signature(x = "unmarkedFrame", i = "numeric", j = "missing", drop = "missing"): ...

[signature(x = "unmarkedFrame", i = "numeric", j = "numeric", drop = "missing"): ...

[signature(x = "unmarkedFrame", i = "missing", j = "numeric", drop = "missing"): ...

getY signature(object = "unmarkedFrame"): extract y matrix

numSites signature(object = "unmarkedFrame"): extract M

numY signature(object = "unmarkedFrame"): extract ncol(y)

obsCovs signature(object = "unmarkedFrame"): extract observation-level covariates

obsCovs<- signature(object = "unmarkedFrame"): add or modify observation-level covariates

obsNum signature(object = "unmarkedFrame"): extract number of observations

obsToY signature(object = "unmarkedFrame"):

obsToY<- signature(object = "unmarkedFrame"): ...

plot signature(x = "unmarkedFrame", y = "missing"): visualize response variable. Takes additional argument panels which specifies how many panels data should be split over.

show signature(object = "unmarkedFrame"): view data as data.frame

siteCovs signature(object = "unmarkedFrame"): extract site-level covariates

siteCovs<- signature(object = "unmarkedFrame"): add or modify site-level covariates

summary signature(object = "unmarkedFrame"): summarize data

getL signature(object = "unmarkedFrameOccuCOP"): extract L

Note

This is a superclass with child classes for each fitting function.

---

unmarkedFrameDS   *Organize data for the distance sampling model of Royle et al. (2004)*
                          fit by distsamp

Description

Organizes count data along with the covariates and metadata. This S4 class is required by the data
argument of distsamp

Usage

```
unmarkedFrameDS(y, siteCovs=NULL, dist.breaks, tlength, survey,
    unitsIn)
```

Arguments

y	An RxJ matrix of count data, where R is the number of sites (transects) and J is the number of distance classes.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have R rows and one column per covariate
dist.breaks	vector of distance cut-points delimiting the distance classes. It must be of length J+1.
tlength	A vector of length R containing the trasect lengths. This is ignored when survey="point".
survey	Either "point" or "line" for point- and line-transects.
unitsIn	Either "m" or "km" defining the measurement units for *both* dist.breaks and tlength
.	

Details

unmarkedFrameDS is the S4 class that holds data to be passed to the [distsamp](#) model-fitting function.

Value

an object of class unmarkedFrameDS

Note

If you have continuous distance data, they must be "binned" into discrete distance classes, which are delimited by dist.breaks.

Examples

```
# Fake data
R <- 4 # number of sites
J <- 3 # number of distance classes

db <- c(0, 10, 20, 30) # distance break points

y <- matrix(c(
   5,4,3, # 5 detections in 0-10 distance class at this transect
   0,0,0,
```

```
   2,1,1,
   1,1,0), nrow=R, ncol=J, byrow=TRUE)
y

site.covs <- data.frame(x1=1:4, x2=factor(c('A','B','A','B')))
site.covs

umf <- unmarkedFrameDS(y=y, siteCovs=site.covs, dist.breaks=db, survey="point",
    unitsIn="m")            # organize data
umf                         # look at data
summary(umf)                # summarize
fm <- distsamp(~1 ~1, umf)  # fit a model
```

---

unmarkedFrameDSO	*Create an object of class unmarkedFrameDSO that contains data used by distsampOpen.*

Description

Organizes distance sampling data and experimental design information from multiple primary periods along with associated covariates. This S4 class is required by the data argument of [distsampOpen](#)

Usage

```
unmarkedFrameDSO(y, siteCovs=NULL, yearlySiteCovs=NULL, numPrimary,
     primaryPeriod, dist.breaks, tlength, survey, unitsIn)
```

Arguments

y	An MxJT matrix of the repeated count data, where M is the number of sites (i.e., points or transects), J is the number of distance classes and T is the maximum number of primary sampling periods per site
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
yearlySiteCovs	Either a named list of MxT [data.frame](#)s, or a site-major [data.frame](#) with MT rows and 1 column per covariate
numPrimary	Maximum number of observed primary periods for each site
primaryPeriod	An MxJT matrix of integers indicating the primary period of each observation
dist.breaks	vector of distance cut-points delimiting the distance classes. It must be of length J+1
tlength	A vector of length R containing the transect lengths. This is ignored when survey="point"
survey	Either "point" or "line" for point- and line-transects
unitsIn	Either "m" or "km" defining the measurement units for *both* dist.breaks and tlength

Details

unmarkedFrameDSO is the S4 class that holds data to be passed to the distsampOpen model-fitting function. Unlike most unmarked functions, obsCovs cannot be supplied.

If you have continuous distance data, they must be "binned" into discrete distance classes, which are delimited by dist.breaks.

When gamma or omega are modeled using year-specific covariates, the covariate data for the final year will be ignored; however, they must be supplied.

If the time gap between primary periods is not constant, an M by T matrix of integers should be supplied using the primaryPeriod argument.

Value

an object of class unmarkedFrameDSO

---

unmarkedFrameGDR   *Organize data for the combined distance and removal point-count*
                           model of Amundson et al. (2014) fit by gdistremoval

---

Description

Organize data for the combined distance and removal point-count model of Amundson et al. (2014)
fit by gdistremoval

Usage

```
    unmarkedFrameGDR(yDistance, yRemoval, numPrimary=1, siteCovs=NULL, obsCovs=NULL,
               yearlySiteCovs=NULL, dist.breaks, unitsIn, period.lengths=NULL)
```

Arguments

yDistance	An MxTJ matrix of count data, where M is the number of sites (points), T is the number of primary periods (can be 1) and J is the number of distance classes
yRemoval	An MxTJ matrix of count data, where M is the number of sites (points), T is the number of primary periods (can be 1) and J is the number of time removal periods
numPrimary	Number of primary periods in the dataset
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	A [data.frame](#) of covariates that vary at the site level. This should have MxTJ rows and one column per covariate. These covariates are used only by the removal part of the model
yearlySiteCovs	A [data.frame](#) of covariates that vary by site and primary period. This should have MxT rows and one column per covariate
dist.breaks	vector of distance cut-points delimiting the distance classes. It must be of length J+1
unitsIn	Either "m" or "km" defining the measurement units for dist.breaks

period.lengths Optional vector of time lengths of each removal period. Each value in the vector must be a positive integer, and the total length of the vector must be equal to the number of removal periods J. If this is not provided (the default), then all periods are assumed to have an equal length of 1 time unit

Details

unmarkedFrameGDR is the S4 class that holds data to be passed to the gdistremoval model-fitting function.

Value

an object of class unmarkedFrameGDR

Note

If you have continuous distance data, they must be "binned" into discrete distance classes, which are delimited by dist.breaks.

unmarkedFrameMMO   *Create an object of class unmarkedFrameMMO that contains data used by multmixOpen.*

Description

Organizes count data and experimental design information from multiple primary periods along with associated covariates. This S4 class is required by the data argument of multmixOpen

Usage

```
unmarkedFrameMMO(y, siteCovs=NULL, obsCovs=NULL, yearlySiteCovs=NULL,
        numPrimary, type, primaryPeriod)
```

Arguments

y	An MxJT matrix of the repeated count data, where M is the number of sites (i.e., points or transects), J is the number of distance classes and T is the maximum number of primary sampling periods per site
siteCovs	A data.frame of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of data.frames of covariates that vary within sites, or a data.frame with MxJT rows in site-major order.
yearlySiteCovs	Either a named list of MxT data.frames, or a site-major data.frame with MT rows and 1 column per covariate
numPrimary	Maximum number of observed primary periods for each site
type	Either "removal" for removal sampling, "double" for standard double observer sampling, or "depDouble" for dependent double observer sampling
primaryPeriod	An MxJT matrix of integers indicating the primary period of each observation

Details

unmarkedFrameMMO is the S4 class that holds data to be passed to the multmixOpen model-fitting function.

Options for the detection process (type) include equal-interval removal sampling (″removal″), double observer sampling (″double″), or dependent double-observer sampling (″depDouble″). Note that unlike the related functions multinomPois and gmultmix, custom functions for the detection process (i.e., piFuns) are not supported. To request additional options contact the author.

When gamma or omega are modeled using year-specific covariates, the covariate data for the final year will be ignored; however, they must be supplied.

If the time gap between primary periods is not constant, an M by T matrix of integers should be supplied using the primaryPeriod argument.

Value

```

---

unmarkedFrameMPois	*Organize data for the multinomial-Poisson mixture model of Royle (2004) fit by multinomPois*

Description

Organizes count data along with the covariates. This S4 class is required by the data argument of multinomPois

Usage

```
unmarkedFrameMPois(y, siteCovs=NULL, obsCovs=NULL, type, obsToY,
    piFun)
```

Arguments

y	An RxJ matrix of count data, where R is the number of sites (transects) and J is the maximum number of observations per site.
siteCovs	A data.frame of covariates that vary at the site level. This should have R rows and one column per covariate

obsCovs   Either a named list of RxJ [data.frame](s) or a data.frame with RxJ rows and
                 one column per covariate. For the latter format, the covariates should be in
                 site-major order.

type   Either "removal" for removal sampling, "double" for standard double observer
                 sampling, or "depDouble" for dependent double observer sampling. If this ar-
                 gument not specified, the user must provide an obsToY matrix. See details.

obsToY   A matrix describing the relationship between obsCovs and y. This is necessary
                 because under some sampling designs the dimensions of y do not equal the
                 dimensions of each observation level covariate. For example, in double observer
                 sampling there are 3 observations (seen only by observer A, detected only by
                 observer B, and detected by both), but each observation-level covariate can only
                 have 2 columns, one for each observer. This matrix is created automatically if
                 type is specified.

piFun   Function used to compute the multinomial cell probabilities from a matrix of
                 detection probabilities. This is created automatically if type is specified.

Details

unmarkedFrameMPois is the S4 class that holds data to be passed to the multinomPois model-
fitting function.

Value

an object of class unmarkedFrameMPois

unmarkedFrameOccu	*Organize data for the single season occupancy models fit by occu and occuRN*

Description

Organizes detection, non-detection data along with the covariates. This S4 class is required by the data argument of [occu](#) and [occuRN](#)

Usage

```
unmarkedFrameOccu(y, siteCovs=NULL, obsCovs=NULL)
```

Arguments

y	An RxJ matrix of the detection, non-detection data, where R is the number of sites, J is the maximum number of sampling periods per site.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of [data.frame](#)s of covariates that vary within sites, or a [data.frame](#) with RxJ rows in site-major order.

Details

unmarkedFrameOccu is the S4 class that holds data to be passed to the [occu](#) and [occuRN](#) model-fitting function.

Value

an object of class unmarkedFrameOccu

See Also

[unmarkedFrame-class](#), [unmarkedFrame](#), [occu](#), [occuRN](#)

Examples

```
# Fake data
R <- 4 # number of sites
J <- 3 # number of visits
y <- matrix(c(
   1,1,0,
   0,0,0,
   1,1,1,
   1,0,1), nrow=R, ncol=J, byrow=TRUE)
y

site.covs <- data.frame(x1=1:4, x2=factor(c('A','B','A','B')))
site.covs

obs.covs <- list(
   x3 = matrix(c(
      -1,0,1,
      -2,0,0,
      -3,1,0,
      0,0,0), nrow=R, ncol=J, byrow=TRUE),

```

---

unmarkedFrameOccuComm   *Organize data for the community occupancy model fit by occuComm*

Description

Organize detection/non-detection data and covariates for use with the community occupancy model

Usage

```
unmarkedFrameOccuComm(y, siteCovs = NULL, obsCovs = NULL, speciesCovs = NULL)
```

Arguments

y	The detection-nondetection data for multiple species. This data may be in one of two forms: either a named list of S M x J matrices (M = sites, J = occasions, S = species) or an M x J x S array.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate.
obsCovs	Either a named list of [data.frame](#)s of covariates that vary within sites, or a [data.frame](#) with M x J rows in site-major order.
speciesCovs	Covariates that also vary by species. This must be provided as a named list. Each list element can have one of three possible dimensions: a vector of length S (e.g., mean species body mass); a matrix M x S (covariates that vary by site and species); or an array M x J x S (covariates that vary by site, occasion, and species).

Value

an object of class unmarkedFrameOccuComm

summary(umf)
```

---

unmarkedFrameOccuCOP   *Organize data for the occupancy model using count data fit by*
                           occuCOP

Description

Organizes count data along with the covariates. The [unmarkedFrame](#) S4 class required by the `data` argument of [occuCOP](#).

Usage

```
unmarkedFrameOccuCOP(y, L, siteCovs = NULL, obsCovs = NULL)
```

Arguments

y   An MxJ matrix of the count data, where M is the number of sites, J is the maximum number of observation periods (sampling occasions, transects, discretised sessions...) per site.

L   An MxJ matrix of the length of the observation periods. For example, duration of the sampling occasion in hours, duration of the discretised session in days, or length of the transect in meters.

siteCovs   A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate

obsCovs   A named list of dataframes of dimension MxJ, with one dataframe per covariate that varies between sites and observation periods

Details

unmarkedFrameOccuCOP is the [unmarkedFrame](#) S4 class that holds data to be passed to the [occuCOP](#) model-fitting function.

Value

an object of class unmarkedFrameOccuCOP

See Also

[unmarkedFrame-class](#), [unmarkedFrame](#), [occuCOP](#)

Examples

```

))

# Organise data in a unmarkedFrameOccuCOP object
umf <- unmarkedFrameOccuCOP(
  y = y,
  L = L,
  siteCovs = site.covs,
  obsCovs = obs.covs.list
)

# Extract L
getL(umf)

# Look at data
print(umf) # Print the whole data set
print(umf[1, 2]) # Print the data of the 1st site, 2nd observation
summary(umf) # Summarise the data set
plot(umf) # Plot the count of detection events

# L is optional, if absent, it will be replaced by a MxJ matrix of 1
unmarkedFrameOccuCOP(
  y = y,
  siteCovs = site.covs,
  obsCovs = obs.covs.list
)

# Covariates are optional
```

```
unmarkedFrameOccuCOP(y = y)
```

---

unmarkedFrameOccuFP   *Organize data for the single season occupancy models fit by occuFP*

Description

Organizes detection, non-detection data along with the covariates. This S4 class is required by the data argument of [occu](#) and [occuRN](#)

Usage

```
unmarkedFrameOccuFP(y, siteCovs=NULL, obsCovs=NULL, type)
```

Arguments

y	An RxJ matrix of the detection, non-detection data, where R is the number of sites, J is the maximum number of sampling periods per site.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of [data.frame](#)s of covariates that vary within sites, or a [data.frame](#) with RxJ rows in site-major order.
type	A vector with 3 values designating the number of occassions where data is of type 1, type 2, and type 3 - see [occuFP](#) for more details about data types.

Details

unmarkedFrameOccuFP is the S4 class that holds data to be passed to the [occu](#) and [occuRN](#) model-fitting function.

Value

an object of class unmarkedFrameOccuFP

See Also

[unmarkedFrame-class](#), [unmarkedFrame](#), [occuFP](#)

Examples

```
n = 100
o = 10
o1 = 5
y = matrix(0,n,o)
p = .7
r = .5
fp = 0.05
y[1:(n*.5),(o-o1+1):o] <- rbinom((n*o1*.5),1,p)
```

```
y[1:(n*.5),1:(o-o1)] <- rbinom((o-o1)*n*.5,1,r)
y[(n*.5+1):n,(o-o1+1):o] <- rbinom((n*o1*.5),1,fp)
type <- c((o-o1),o1,0)  ### vector with the number of each data type
site <- c(rep(1,n*.5*.8),rep(0,n*.5*.2),rep(1,n*.5*.2),rep(0,n*.8*.5))
occ <- matrix(c(rep(0,n*(o-o1)),rep(1,n*o1)),n,o)
site <- data.frame(habitat = site)
occ <- list(METH = occ)

umf1 <- unmarkedFrameOccuFP(y,site,occ, type = type)

m1 <- occuFP(detformula = ~ METH, FPformula = ~1, stateformula = ~ habitat, data = umf1)
```

---

unmarkedFrameOccuMS   *Organize data for the multi-state occupancy model fit by occuMS*

Description

Organizes multi-state occupancy data (currently single-season only) along with covariates. This S4 class is required by the data argument of [occuMS](#)

Usage

```
unmarkedFrameOccuMS(y, siteCovs=NULL, obsCovs=NULL,
                      numPrimary=1, yearlySiteCovs=NULL)
```

Arguments

y	An MxR matrix of multi-state occupancy data for a species, where M is the number of sites and R is the maximum number of observations per site (across all primary and secondary periods, if you have multi-season data). Values in y should be integers ranging from 0 (non-detection) to the number of total states - 1. For example, if you have 3 occupancy states, y should contain only values 0, 1, or 2.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of [data.frame](#)s of covariates that vary within sites, or a [data.frame](#) with MxR rows in the ordered by site-observation (if single-season) or site-primary period-observation (if multi-season).
numPrimary	Number of primary time periods (e.g. seasons) for the dynamic or multi-season version of the model. There should be an equal number of secondary periods in each primary period.
yearlySiteCovs	A data frame with one column per covariate that varies among sites and primary periods (e.g. years). It should have MxT rows where M is the number of sites and T the number of primary periods, ordered by site-primary period. These covariates only used for dynamic (multi-season) models.

Details

unmarkedFrameOccuMS is the S4 class that holds data to be passed to the occuMS model-fitting function.

Value

an object of class unmarkedFrameOccuMS

Author(s)

Ken Kellner <contact@kenkellner.com>

unmarkedFrame-class, unmarkedFrame, occuMS

Examples

```
# Fake data
#Parameters
N <- 100; J <- 3; S <- 3
psi <- c(0.5,0.3,0.2)
p11 <- 0.4; p12 <- 0.25; p22 <- 0.3

#Simulate state
z <- sample(0:2, N, replace=TRUE, prob=psi)

#Simulate detection
y <- matrix(0,nrow=N,ncol=J)
for (n in 1:N){
  probs <- switch(z[n]+1,
                  c(0,0,0),
                  c(1-p11,p11,0),
                  c(1-p12-p22,p12,p22))

  if(z[n]>0){
    y[n,] <- sample(0:2, J, replace=TRUE, probs)
  }
}

#Covariates
site_covs <- as.data.frame(matrix(rnorm(N*2),ncol=2)) # nrow = # of sites
obs_covs <- as.data.frame(matrix(rnorm(N*J*2),ncol=2)) # nrow = N*J

#Build unmarked frame
umf <- unmarkedFrameOccuMS(y=y,siteCovs=site_covs,obsCovs=obs_covs)

umf                     # look at data
summary(umf)            # summarize
plot(umf)               # visualize
umf@numStates           # check number of occupancy states detected
```

---

unmarkedFrameOccuMulti

Organize data for the multispecies occupancy model fit by occuMulti

---

Description

Organizes detection, non-detection data for multiple species along with the covariates. This S4 class is required by the data argument of occuMulti

Usage

```
unmarkedFrameOccuMulti(y, siteCovs=NULL, obsCovs=NULL,
                       maxOrder)
```

Arguments

y	A list (optionally a named list) of length S where each element is an MxJ matrix of the detection, non-detection data for one species, where M is the number of sites, J is the maximum number of sampling periods per site, and S is the number of species in the analysis.
siteCovs	A data.frame of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of data.frames of covariates that vary within sites, or a data.frame with MxJ rows in site-major order.
maxOrder	Optional; specify maximum interaction order. Defaults to number of species (all possible interactions). Reducing this value may speed up creation of unmarked frame if you aren't interested in higher-order interactions.

Details

unmarkedFrameOccuMulti is the S4 class that holds data to be passed to the occuMulti model-fitting function.

Value

an object of class unmarkedFrameOccuMulti

unmarkedFrame-class, unmarkedFrame, occuMulti

Examples

```
# Fake data
S <- 3 # number of species
M <- 4 # number of sites
J <- 3 # number of visits

y <- list(matrix(rbinom(M*J,1,0.5),M,J), # species 1
          matrix(rbinom(M*J,1,0.5),M,J), # species 2
          matrix(rbinom(M*J,1,0.2),M,J)) # species 3

site.covs <- data.frame(x1=1:4, x2=factor(c('A','B','A','B')))
site.covs

umf <- unmarkedFrameOccuMulti(y=y, siteCovs=site.covs,
    obsCovs=NULL)   # organize data
umf                      # look at data
summary(umf)             # summarize
plot(umf)                # visualize
#fm <- occu(~1 ~1, umf)  # fit a model
```

---

unmarkedFrameOccuTTD   *Create an unmarkedFrameOccuTTD object for the time-to-detection model fit by occuTTD*

Description

Organizes time-to-detection occupancy data along with covariates. This S4 class is required by the data argument of [occuTTD](#)

Usage

```
unmarkedFrameOccuTTD(y, surveyLength, siteCovs=NULL, obsCovs=NULL,
                     numPrimary=1, yearlySiteCovs=NULL)
```

Arguments

y	An MxR matrix of time-to-detection data for a species, where M is the number of sites and R is the maximum number of observations per site (across all primary periods and observations, if you have multi-season data). Values in y should be positive.
surveyLength	The maximum length of a survey, in the same units as y. You can provide either a single value (if all surveys had the same max length), or a matrix matching the dimensions of y (if surveys had different max lengths).
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate

obsCovs   Either a named list of [data.frame](#)s of covariates that vary within sites, or a
                 [data.frame](#) with MxR rows in the ordered by site-observation (if single-season)
                 or site-primary period-observation (if multi-season).

numPrimary   Number of primary time periods (e.g. seasons) for the dynamic or multi-season
                 version of the model. There should be an equal number of secondary periods in
                 each primary period.

yearlySiteCovs   A data frame with one column per covariate that varies among sites and primary
                 periods (e.g. years). It should have MxT rows where M is the number of sites
                 and T the number of primary periods, ordered by site-primary period. These
                 covariates only used for dynamic (multi-season) models.

Details

unmarkedFrameOccuTTD is the S4 class that holds data to be passed to the [occuTTD](#) model-fitting
function.

Value

an object of class unmarkedFrameOccuTTD

Note

If the time-to-detection values in y are very large (e.g., because they are expressed as numbers of
seconds) you may have issues fitting models. An easy solution is to convert your units (e.g., from
seconds to decimal minutes) to keep the values as close to 0 as possible.

Author(s)

Ken Kellner <contact@kenkellner.com>

Examples

```
# For a single-season model
N <- 100 #Number of sites
psi <- 0.4 #Occupancy probability
lam <- 7 #Parameter for exponential distribution of time to detection
Tmax <- 10 #Maximum survey length

z <- rbinom(N, 1, psi) #Simulate occupancy
y <- rexp(N, 1/lam) #Simulate time to detection
y[z==0] <- Tmax
y[y>Tmax] <- Tmax

sc <- as.data.frame(matrix(rnorm(N*2),ncol=2)) #Site covs
oc <- as.data.frame(matrix(rnorm(N*2),ncol=2)) #obs covs

umf <- unmarkedFrameOccuTTD(y=y, surveyLength=Tmax, siteCovs=sc, obsCovs=oc)
```

---

unmarkedFramePCO	*Create an object of class unmarkedFramePCO that contains data used by pcountOpen.*

Description

Organizes repeated count data along with the covariates and possibly the dates on which each survey was conducted. This S4 class is required by the data argument of [pcountOpen](#)

Usage

```
unmarkedFramePCO(y, siteCovs=NULL, obsCovs=NULL, yearlySiteCovs,
    numPrimary, primaryPeriod)
```

Arguments

y	An MxJT matrix of the repeated count data, where M is the number of sites, J is the maximum number of secondary sampling periods per site and T is the maximum number of primary sampling periods per site.
siteCovs	A [data.frame](#) of covariates that vary at the site level. This should have M rows and one column per covariate
obsCovs	Either a named list of [data.frame](#)s of covariates that vary within sites, or a [data.frame](#) with MxJT rows in site-major order.
yearlySiteCovs	Either a named list of MxT [data.frame](#)s, or a site-major [data.frame](#) with MT rows and 1 column per covariate.
numPrimary	Maximum number of observed primary periods for each site
primaryPeriod	matrix of integers indicating the primary period of each survey.

Details

unmarkedFramePCO is the S4 class that holds data to be passed to the [pcountOpen](#) model-fitting function.

The unmarkedFramePCO class is similar to the unmarkedFramePCount class except that it contains the dates for each survey, which needs to be supplied .

Value

an object of class unmarkedFramePCO

unmarkedModSel-class   *unmarkedModSel class and methods*

Description

The unmarkedModSel class and associated methods

Slots

Full data.frame with formula, estimates, standard errors and model selection information. Converge is optim convergence code. CondNum is model condition number. n is the number of sites. delta is delta AIC. cumltvWt is cumulative AIC weight. Rsq is Nagelkerke's (1991) R-squared index, which is only returned when the nullmod argument is specified.

Names matrix referencing column names of estimates (row 1) and standard errors (row 2).

Methods

show Print the AIC model selection table

coef Data frame of coefficients from all models in model selection table

SE Data frame of coefficient SEs from all models in model selection table

See Also

[modSel](#)

Examples

```
data(linetran)

```

---

unmarkedMultFrame   *Create an unmarkedMultFrame, unmarkedFrameGMM, unmarked-*
                            FrameGDS, or unmarkedFrameGPC object

---

Description

These functions construct unmarkedFrames for data collected during primary and secondary sampling periods.

Usage

```
unmarkedMultFrame(y, siteCovs, obsCovs, numPrimary, yearlySiteCovs)
unmarkedFrameGMM(y, siteCovs, obsCovs, numPrimary, yearlySiteCovs, type,
  obsToY, piFun)
unmarkedFrameGDS(y, siteCovs, numPrimary, yearlySiteCovs, dist.breaks,
  survey, unitsIn, tlength)
unmarkedFrameGPC(y, siteCovs, obsCovs, numPrimary, yearlySiteCovs)
```

Arguments

y	A matrix of the observed data.
siteCovs	Data frame of covariates that vary at the site level.
obsCovs	Data frame of covariates that vary within site-year-observation level.
numPrimary	Number of primary time periods (seasons in the multiseason model).
yearlySiteCovs	Data frame containing covariates at the site-year level.
type	Set to "removal" for constant-interval removal sampling, "double" for standard double observer sampling, or "depDouble" for dependent double observer sampling. This should be not be specified for other types of survey designs.
obsToY	A matrix specifying relationship between observation-level covariates and response matrix
piFun	A function converting an MxJ matrix of detection probabilities into an MxJ matrix of multinomial cell probabilities.
dist.breaks	see [unmarkedFrameDS](#)
survey	see [unmarkedFrameDS](#)
unitsIn	see [unmarkedFrameDS](#)
tlength	see [unmarkedFrameDS](#)

Details

unmarkedMultFrame objects are used by colext.

unmarkedFrameGMM objects are used by gmultmix.

unmarkedFrameGDS objects are used by gdistsamp.

unmarkedFrameGPC objects are used by gpcount.

For a study with *M* sites, *T* years, and a maximum of *J* observations per site-year, the data can be supplied in a variety of ways but are stored as follows. y is an $M \times TJ$ matrix, with each row corresponding to a site. siteCovs is a data frame with M rows. yearlySiteCovs is a data frame with MT rows which are in site-major, year-minor order. obsCovs is a data frame with MTJ rows, which are ordered by site-year-observation, so that a column of obsCovs corresponds to as.vector(t(y)), element-by-element. The number of years must be specified in numPrimary.

If the data are in long format, the convenience function formatMult is useful for creating the unmarkedMultFrame.

unmarkedFrameGMM and unmarkedFrameGDS are superclasses of unmarkedMultFrame containing information on the survey design used that resulted in multinomial outcomes. For unmarkedFrameGMM and constant-interval removal sampling, you can set type="removal" and ignore the arguments obsToY and piFun. Similarly, for double-observer sampling, setting type="double" or type="depDouble" will automatically create an appropiate obsToY matrix and piFuns. For all other situations, the type argument of unmarkedFrameGMM should be ignored and the obsToY and pi-Fun arguments must be specified. piFun must be a function that converts an MxJ matrix of detection probabilities into an MxJ matrix of multinomial cell probabilities. obsToY is a matrix describing how the obsCovs relate to the observed counts y. For further discussion and examples see the help page for multinomPois and piFuns.

unmarkedFrameGMM and unmarkedFrameGDS objects can be created from an unmarkedMultFrame using the "as" conversion method. See examples.

Value

an unmarkedMultFrame or unmarkedFrameGMM object

Note

Data used with colext, gmultmix, and gdistsamp may be collected during a single year, so yearlySiteCovs may be a misnomer is some cases.

    siteCovs = data.frame(site=site),
    obsCovs=list(occasion=occasions),
    yearlySiteCovs=data.frame(year=c(t(years))),
    numPrimary=T, obsToY=o2y, piFun="instRemPiFun")

str(umfGMM2)
```

---

unmarkedPower-methods   *Methods for unmarkedPower objects*

Description

Various functions to summarize unmarkedPower objects

Usage

```
## S4 method for signature 'unmarkedPower'
show(object)
## S4 method for signature 'unmarkedPower'
summary(object, alpha, showIntercepts = FALSE, ...)
## S4 method for signature 'unmarkedPower,missing'
plot(x, y, alpha, showIntercepts = FALSE, ...)
```

Arguments

`object, x`	An object of class `unmarkedPower` created with the `powerAnalysis` function
`alpha`	Desired Type I error rate. If not provided, defaults to the value specified when calling `powerAnalysis`.
`showIntercepts`	Show intercepts output? This is rarely useful.
`y`	Not currently used.
`...`	Not currently used.

Value

For `show` and `summary`, summary output is printed to the console. For `plot`, a visualization of the summary output is created.

unmarkedPowerList   *Summarize a series of unmarked power analyses*

Description

A list of power analyses created with `powerAnalysis` can be combined using `unmarkedPowerList`, allowing comparison e.g. between different study designs/sample sizes. A series of methods for `unmarkedPowerList` objects are available including a `plot` method.

Usage

```
## S4 method for signature 'unmarkedPower'
unmarkedPowerList(object, ...)
## S4 method for signature 'unmarkedPowerList'
show(object)
## S4 method for signature 'unmarkedPowerList'
summary(object, showIntercepts = FALSE, ...)
## S4 method for signature 'unmarkedPowerList,ANY'
plot(x, power=NULL, param=NULL, ...)
```

Arguments

`object, x`	For unmarkedPowerList, an unmarkedPower object. For show, summary, plot, an unmarkedPowerList object.
`showIntercepts`	Show intercepts output? This is rarely useful.
`power`	If specified, adds a dotted line to the plot at this target power value.
`param`	When plotting, the model parameter to plot power vs. sample size for. By default this is the first parameter.
`...`	For unmarkedPowerList, other unmarkedPower objects to combine into the list.

Value

A unmarkedPowerList object, a summary of the object in the console, or a summary plot, depending on the method

Examples

```
## Not run:

# Build unmarkedFrame
umf <- unmarkedFrameOccu(y = matrix(NA, 300, 8),
                         siteCovs = data.frame(elev=rnorm(300)))

# Run power analyses
cf <- list(state = c(0, -0.4), det = 0)
pa1 <- powerAnalysis(umf, model=occu, formula=~1~elev, effects=cf)
pa2 <- powerAnalysis(umf[1:100,], model=occu, formula=~1~elev, effects=cf)

# Combine them into a list
(pl <- unmarkedPowerList(pa1, pa2))
```

```
# Look at summary plot for elev effect
plot(pl, power=0.8, param='elev')

## End(Not run)
```

---

unmarkedRanef-class   *Class* "unmarkedRanef"

Description

Stores the estimated posterior distributions of the latent abundance or occurrence variables.

Objects from the Class

Objects can be created by calls of the form [ranef](#).

Slots

post: An [array](#) with nSites rows and Nmax (K+1) columns and nPrimaryPeriod slices

Methods

confint signature(object = "unmarkedRanef"): Compute confidence intervals.

plot signature(x = "unmarkedRanef", y = "missing"): Plot the posteriors using xyplot

show signature(object = "unmarkedRanef"): Display the modes and confidence intervals

Warnings

Empirical Bayes methods can underestimate the variance of the posterior distribution because they do not account for uncertainty in the hyperparameters (lambda or psi). Simulation studies indicate that the posterior mode can exhibit (3-5 percent) negatively bias as a point estimator of site-specific abundance. It appears to be safer to use the posterior mean even though this will not be an integer in general.

vcov-methods   *Methods for Function vcov in Package 'unmarked'*

Description

Extract variance-covariance matrix from a fitted model.

Methods

object = "linCombOrBackTrans" See [linearComb-methods](#)

object = "unmarkedEstimate" See [unmarkedEstimate-class](#)

object = "unmarkedFit" A fitted model

---

vif   *Compute Variance Inflation Factors for an unmarkedFit Object.*

Description

Compute the variance inflation factors (VIFs) for covariates in one level of the model (i.e., occupancy or detection). Calculation of VIFs follows the approach of function vif in package car, using the correlation matrix of fitted model parameters.

Usage

```
vif(mod, type)
```

Arguments

mod	An unmarked fit object.
type	Level of the model for which to calculate VIFs (for example, 'state')

Value

A named vector of variance inflation factor values for each covariate.

[-methods   *Methods for bracket extraction [in Package 'unmarked'*

Description

Methods for bracket extraction [in Package 'unmarked'

Usage

```
## S4 method for signature 'unmarkedEstimateList,ANY,ANY,ANY'
x[i, j, drop]
## S4 method for signature 'unmarkedFit,ANY,ANY,ANY'
x[i, j, drop]
## S4 method for signature 'unmarkedFrame,numeric,numeric,missing'
x[i, j]
## S4 method for signature 'unmarkedFrame,list,missing,missing'
x[i, j]
## S4 method for signature 'unmarkedMultFrame,missing,numeric,missing'
x[i, j]
## S4 method for signature 'unmarkedMultFrame,numeric,missing,missing'
x[i, j]
## S4 method for signature 'unmarkedFrameGMM,numeric,missing,missing'
x[i, j]
## S4 method for signature 'unmarkedFrameGDS,numeric,missing,missing'
x[i, j]
## S4 method for signature 'unmarkedFramePCO,numeric,missing,missing'
x[i, j]
```

Arguments

x	Object of appropriate S4 class
i	Row numbers
j	Observation numbers (eg occasions, distance classes, etc...)
drop	Not currently used

Methods

x = "unmarkedEstimateList", i = "ANY", j = "ANY", drop = "ANY" Extract a unmarkedEstimate object from an unmarkedEstimateList by name (either 'det' or 'state')

x = "unmarkedFit", i = "ANY", j = "ANY", drop = "ANY" Extract a unmarkedEstimate object from an unmarkedFit by name (either 'det' or 'state')

x = "unmarkedFrame", i = "missing", j = "numeric", drop = "missing" Extract observations from an unmarkedFrame.

x = "unmarkedFrame", i = "numeric", j = "missing", drop = "missing" Extract rows from an unmarkedFrame

x = "unmarkedFrame", i = "numeric", j = "numeric", drop = "missing" Extract rows and observations from an unmarkedFrame

x = "unmarkedMultFrame", i = "missing", j = "numeric", drop = "missing" Extract primary sampling periods from an unmarkedMultFrame

x = "unmarkedFrame", i = "list", j = "missing", drop = "missing" List is the index of observations to subset for each site.

x = "unmarkedMultFrame", i = "numeric", j = "missing", drop = "missing" Extract rows (sites) from an unmarkedMultFrame

x = "unmarkedGMM", i = "numeric", j = "missing", drop = "missing" Extract rows (sites) from an unmarkedFrameGMM object

x = "unmarkedGDS", i = "numeric", j = "missing", drop = "missing" Extract rows (sites) from an unmarkedFrameGDS object

x = "unmarkedPCO", i = "numeric", j = "missing", drop = "missing" Extract rows (sites) from an unmarkedFramePCO object

Examples

```
data(mallard)
mallardUMF <- unmarkedFramePCount(mallard.y, siteCovs = mallard.site,
obsCovs = mallard.obs)
summary(mallardUMF)

mallardUMF[1:5,]
mallardUMF[,1:2]
mallardUMF[1:5, 1:2]
```
